HIDDEN GIBBS MEASURES ON SHIFT SPACES OVER COUNTABLE
ALPHABETS

GODOFREDO IOMMI, CAMILO LACALLE, AND YUKI YAYAMA

Abstract. We study the thermodynamic formalism for particular types of sub-additive sequences
on a class of subshifts over countable alphabets. The subshifts we consider include factors of
irreducible countable Markov shifts under certain conditions. We show the variational principle
for topological pressure. We also study conditions for the existence and uniqueness of invariant
ergodic Gibbs measures and the uniqueness of equilibrium states. As an application, we extend
the theory of factors of (generalized) Gibbs measures on subshifts on finite alphabets to that on
certain subshifts over countable alphabets.

1. Introduction

Thermodynamic formalism is an area of ergodic theory which addresses the problem of choosing
relevant invariant measures among the, sometimes very large, set of invariant probabilities. This
theory was brought from statistical mechanics into dynamics in the early seventies by Ruelle and
Sinai among others [Ru, Si]. The powerful formalism developed to study equilibrium of systems
consisting of a large number of particles (e.g. gases) has been surprisingly efficient to describe
certain dynamical systems that exhibit complicated behavior. The theory has been developed in
several directions. Originally the dynamical system was assumed to be defined on a compact set and
the observable was a continuous function. Both assumptions have been relaxed over the years. For
example, Gurevich [Gu1, Gu2, GS], Mauldin and Urbański [MU1, MU2] and Sarig [S1, S3, S3] have
developed thermodynamic formalism in the non-compact setting of countable Markov shifts. Since
there exists a wide range of relevant dynamical systems that can be coded with countable Markov
shifts, this theory has had relevant applications. Other extension of thermodynamical formalism to
non-compact settings was developed by Pesin and Pitskel [PeP]. In that case, the system is not
assumed to have any Markov structure but it has to be the restriction of a continuous map defined
on a compact set. Also, the observables have to have continuous extensions (therefore observables
are assumed to be bounded). In a different direction, the theory was extended to consider not only
a single observable but instead a sequence of them. Certain additivity assumptions were required
on the sequence in order for the ergodic theorems to hold. This circle of ideas was called non-
additive thermodynamic formalism. It was originally formulated by Falconer [F1] with the purpose
of applying it in the study of the dimension theory of non-conformal dynamical systems. Ever
since, different additivity assumptions have been considered in the sequence. For example, Barreria
[B1, B2, B3] developed the theory assuming a strong additivity assumption called almost-additivity.
Mummert [M] also obtained results in this direction. Cao, Feng and Huang [CFH] studied the case in which the sequence was only assumed to be sub-additive. More generally, Feng and Huang [FH] extended the theory to handle asymptotically sub-additive sequences. Over the last few years, thermodynamic formalism for non-compact dynamical systems and sequences of observables has been developed. Iommi and Yayama [IY1, IY2] have studied thermodynamic formalism for almost-additive sequences on (non-compact) countable Markov shifts. Also, Käenmäki and Reeve [KR] studied the formalism for sequences of potentials under weaker additivity assumptions but for the full shift over a countable alphabet.

In this paper, we further develop the theory. We consider particular types of sub-additive sequences on a fairly general class of subshifts. We call this class the class of countable sofic shifts, where a countable sofic shift is defined as the image of a countable Markov shift under a one-block factor map with an additional condition (see Section 2.3). This class therefore generalizes the concept of a sofic shift over a finite alphabet. We stress that this dynamical system is non-Markov and it is defined on a non-compact space. Even in the case of a single observable, several of our results are new, to the best of our knowledge. The types of sub-additive sequences we consider are generalizations of continuous functions with tempered variation on subshifts satisfying the weak specification property (see Section 2.2 for details). In Section 2, we propose a definition of the topological pressure and compare it with the Gurevich pressure. Then we prove the corresponding variational principle in Theorems 4.2 and 4.3 in Section 4. In particular, Section 4.2 studies a variational principle for sequences with tempered variation defined on finitely irreducible subshifts (see Definition 2.3) which preserve a certain finiteness property found in compact spaces. In Section 4.1, the variational principle is also studied in the case when the Bowen sequences (see Definition 2.7) are defined on countable Markov shifts which are not necessarily finitely irreducible. We see that if the topological pressure of the sequence considered in Section 4.1 is finite, then the space on which it is defined is finitely irreducible. Hence, this type of sequence is suitable for studying Gibbs measures. In Section 5, we show under some assumptions the existence and uniqueness of Gibbs measures on finitely irreducible countable sofic shifts, together with uniqueness of the Gibbs equilibrium states (see Theorem 5.1). Our results extend those in [KR], encompassing more general classes of sequences and far more general dynamical systems.

Differences with the work in [IY1, IY2] are discussed in Section 3.1. In particular, not every almost-additive sequence studied in [IY1] is in the class of sequences we study here (see Example 3.2). This phenomenon is different from what is observed in the compact case, in which every almost-additive sequence satisfies the assumptions we consider. Examples of the kinds of sequences we study are presented and compared with almost-additive sequences in Section 3, and these are studied especially with the variational principle in Section 4.

One of the main applications of the thermodynamic formalism studied in this article is to develop the theory of factors of Gibbs measures on shift spaces over countable alphabets. An important question in the area is to determine under which conditions the (generalized) Gibbs property is preserved under a one-block factor map. For Gibbs measures for continuous functions on subshifts over finite alphabets, this problem has been studied widely, for example, by Chazottes and Ugalde [CU1, CU2], Kempton and Pollicott [PK], Kempton [K], Piranio [P], Jung [J2], Verbitskiy [V] and Yoo [Yo]. For generalized Gibbs measures for sequences on subshifts over finite alphabets, this type of question has been addressed by Barral and Feng [BF], Feng [Fe4] and Yayama [Y1, Y2], especially in connection with dimension problems on non-conformal repellers. In Section 6, we address this question in the (non-compact and non-Markov) context of finitely irreducible countable sofic shifts. Applying the results of Sections 4 and 5, in Theorem 6.1 we show that under certain conditions a factor of a unique invariant Gibbs measure for an almost-additive sequence on a finitely irreducible countable sofic shift is a Gibbs measure for a type of sequence we study in Section 2.2. The most
general form of the variational principle concerning factor maps in this paper is given in Theorem 6.2. The results in Section 6 generalize some results of [Y2]. Finally, in Section 7, applications are given to the study of some problems in dimension theory, in particular, product of matrices and the singular value function.

2. Background

2.1. Subshifts on countable alphabets and specification properties. This section is devoted to recall basic notions of symbolic dynamics. We discuss countable Markov shifts, factor maps and different specification properties in this setting. For more details we refer the reader to [LM, BP]. Let \((t_{ij})_{i,j \in \mathbb{N}}\) be a transition matrix of zeros and ones (with no row and no column made entirely of zeros). The associated (one-sided) countable Markov shift \((\Sigma, \sigma)\) is the set

\[ \Sigma := \{(x_n)_{n \in \mathbb{N}} : t_{x_n, x_{n+1}} = 1 \text{ for every } n \in \mathbb{N}\}, \]

together with the shift map \(\sigma : \Sigma \to \Sigma\) defined by \(\sigma(x) = x'\), for \(x = (x_n)_{n=1}^{\infty}, x' = (x'_n)_{n=1}^{\infty}\) with \(x'_n = x_{n+1}\) for all \(n \in \mathbb{N}\). If for every \((i, j) \in \mathbb{N}^2\) the transition matrix satisfies \(t_{ij} = 1\), then we say that the corresponding countable Markov shift is the full shift on a countable alphabet.

An allowable word of length \(n \in \mathbb{N}\) for \(\Sigma\) is a string \(i_1 \ldots i_n\) where \(t_{i_j, i_{j+1}} = 1\) for every \(j \in \{1, \ldots, n - 1\}\). For each \(n \in \mathbb{N}\), denote by \(B_n(\Sigma)\) the set of allowable words of length \(n\) of \(\Sigma\). For \(i_1 \ldots i_n \in B_n(\Sigma)\), we define a cylinder set \([i_1 \ldots i_n]\) of length \(n\) by

\[ [i_1 \ldots i_n] = \{x \in \Sigma : x_j = i_j \text{ for } 1 \leq j \leq n\}. \]

We endow \(\Sigma\) with the topology generated by cylinder sets. This is a metrizable space. The following metric generates the cylinder topology. Let \(d\) on \(\Sigma\) by \(d(x, x') = 1/2^k\) if \(x_i = x'_i\) for all \(1 \leq i \leq k\) and \(x_{k+1} \neq x'_{k+1}\), \(d(x, x') = 1\) if \(x_1 \neq x'_1\), and \(d(x, x') = 0\) otherwise. We stress that, in general, \(\Sigma\) is a non-compact space.

We can drop the Markov structure and define subshifts on countable alphabets. Let \(X\) be a closed subset of the full shift \(\Sigma\). If \(X\) is \(\sigma\)-invariant, that is \(\sigma(X) \subseteq X\), then we say that \((X, \sigma|_X)\) is a subshift and we write \(\sigma|_X\) instead of \(\sigma|_X\). In particular, if \(X\) is not a subset of the full shift on a finite alphabet, then we say that \((X, \sigma|_X)\) is a subshift on a countable alphabet. We also write \((X, \sigma)\) for simplicity. The set \(X\) is endowed with the topology induced by \(\Sigma\). In this context the set of allowable words of length \(n\) of \(X\) is defined by

\[ B_n(X) := \{i_1 \ldots i_n \in B_n(\Sigma) : [i_1 \ldots i_n] \cap X \neq \emptyset\}. \]

For an allowable word \(w = i_1 \ldots i_n\) we denote by \(|w|\) its length, \(|i_1 \ldots i_n| = n\). Given a subshift \((X, \sigma)\) on a countable alphabet, we now define the language of \(X\). The word of length \(n = 0\) of \(X\) is called the empty word and it is denoted by \(\varepsilon\). The language of \(X\) is the set \(B(X) = \bigcup_{n=0}^{\infty} B_n(X)\), i.e., the union of all allowable words of \(X\) and the empty word \(\varepsilon\).

We now define several notions of specification that generalize the one first introduced by Bowen [Bo] with the purpose of proving that there exits a unique measure of maximal entropy for a large class of compact subshifts. Our definitions are given in terms of the language of \(X\).

**Definition 2.1.** We say that a subshift \((X, \sigma)\) on a countable alphabet is irreducible if for any allowable words \(u, v \in B(X)\), there exists an allowable word \(w \in B(X)\) such that \(uwv \in B(X)\).

**Definition 2.2.** We say that a subshift \((X, \sigma)\) on a countable alphabet has the weak specification property if there exists \(p \in \mathbb{N}\) such that for any allowable words \(u, v \in B(X)\), there exist \(0 \leq k \leq p\) and \(w \in B_k(X)\) such that \(uwv \in B(X)\). If in addition, \(k = p\) for any \(u\) and \(v\), then \(X\) has the strong specification property. We call such \(p\) a weak (strong, respectively) specification number.

**Definition 2.3.** A subshift \((X, \sigma)\) is finitely irreducible if there exist \(p \in \mathbb{N}\) and a finite subset \(W_1 \subset \bigcup_{n=0}^{p} B_n(X)\) such that for every \(u, v \in B(X)\), there exists \(w \in W_1\) such that \(uwv \in B(X)\).
Definition 2.4. A subshift \((X, \sigma)\) is finitely primitive if there exist \(p \in \mathbb{N}\) and a finite subset \(W_1 \subset B_p(X)\) such that for every \(u, v \in B(X)\), there exists \(w \in W_1\) such that \(uwv \in B(X)\).

Remark 2.1. Note that the weak specification property does not imply topologically mixing. However, if \((\Sigma, \sigma)\) is a topologically mixing subshift of finite type defined on a finite alphabet with the weak specification property, then it has the strong specification property (see [J1, Lemma 3.2]). The class of general shifts on finite alphabets with the weak specification property include irreducible sofic shifts (see [J1] and Definition 2.11).

As it is clear from the definition, the notion of finitely primitive (see Definition 2.4) is essentially the same as that of specification introduced by Bowen [Bo] in a non-compact symbolic setting. There is a closely related class of countable Markov shifts studied by Sarig [S3].

Definition 2.5. A countable Markov shift \((\Sigma, \sigma)\) is said to satisfy the big images and preimages property (BIP property) if there exists \(\{b_1, b_2, \ldots, b_n\}\) in the alphabet \(S\) such that for every \(a \in S\) there exist \(i, j \in \{1, \ldots, n\}\) such that \(t_{b_i}ab_{b_j} = 1\).

Remark 2.2. If the countable Markov shift \((\Sigma, \sigma)\) satisfies the BIP property, then for every symbol in the alphabet, say \(a\), there exist \(b_i, b_j \in \{b_1, b_2, \ldots, b_n\}\) such that \(b_i a\) and \(a b_j\) are allowable words. Note, however, that a system with the BIP property can have more than one transitive component. Indeed, if \(\Sigma\) is the disjoint union of two full shifts on countable alphabets, then it satisfies the BIP property and it has two transitive components.

Nevertheless, as noted by Sarig [S3, p.1752] and by Mauldin and Urbański [MU2], under the following dynamical assumption both notions coincide. A countable Markov shift is topologically mixing, i.e., for each pair \(x, y \in \mathbb{N}\), there exists \(N \in \mathbb{N}\) such that for every \(n > N\) there is an allowable word \(i_1 \ldots i_n \in B_n(\Sigma)\) such that \(i_1 = x, i_n = y\).

Lemma 2.1. If \((\Sigma, \sigma)\) is a topologically mixing countable Markov shift with the BIP property, then it is finitely primitive.

Proof. Let \(a, c \in A\) be two symbols of the alphabet. Since \((\Sigma, \sigma)\) is BIP, there exist \(b_i, b_j \in \{b_1, b_2, \ldots, b_n\}\) in the alphabet, such that \(ab_i, b_j c\) are allowable words. Since \((\Sigma, \sigma)\) is topologically mixing, for each pair \(b_i, b_r \in \{b_1, b_2, \ldots, b_n\}\), there exists \(N_{l,r} \in \mathbb{N}\) such that for every \(k > N_{l,r}\) there is a word \(w_{l,r}^k \in B_k(\Sigma)\) such that \(b_l w_{l,r}^k b_r \in B_{k+2}(\Sigma)\). Let \(N := \max\{N_{l,r} : l, r \in \{1, \ldots, n\}\} + 1\) and consider the set \(\mathcal{F} := \{b_j w_{j,i}^N b_i : i, j \in \{1, \ldots, n\}\}\). Then, for any pair of allowable words \(u \in B_l(\Sigma), v \in B_m(\Sigma)\) there exists \(b_j w_{j,i}^N b_i \in \mathcal{F}\) such that \(u b_j w_{j,i}^N b_i v\) is an allowable word. The result now follows since every word in \(\mathcal{F}\) has length \(N + 2\). □

Remark 2.3. Note that if \((\Sigma, \sigma)\) satisfies the strong specification property then it is topologically mixing and has infinite entropy. On the other hand, if \((\Sigma, \sigma)\) satisfies the weak specification property then it is irreducible and has infinite entropy (see Section 4).

2.2. Pressure for a class of sequences of continuous functions. In this section, we provide two definitions of pressure of sequences of continuous functions defined on non-compact subshifts. We prove that under fairly general assumptions both coincide. Let \((X, \sigma)\) be a subshift on a countable alphabet. For each \(n \in \mathbb{N}\), let \(f_n : X \to \mathbb{R}^+\) be a continuous function and \(\mathcal{F} = \{\log f_n\}_{n=1}^\infty\) a sequence of continuous functions on \(X\). In order to develop thermodynamic formalism and to be able to apply ergodic theorems, additivity assumptions are required on the sequences.
Definition 2.6. A sequence \( F = \{ \log f_n \}_{n=1}^{\infty} \) of continuous functions on \( X \) is called almost-additive if there exists a constant \( C \geq 0 \) such that for every \( n, m \in \mathbb{N}, x \in X \), \( F \) satisfies
\[
 f_{n+m}(x) \leq f_n(x)f_m(\sigma^n x)e^C
\]
and
\[
f_n(x)f_m(\sigma^n x)e^{-C} \leq f_{n+m}(x).
\]
In particular, \( F \) is called sub-additive if \( F \) satisfies (2.1) with \( C = 0 \) and \( F \) is additive if \( F \) satisfies (2.1) and (2.2) with \( C = 0 \). Note that we have (2.1) if and only if the sequence \( F + C = \{ \log(e^Cf_n) \}_{n=1}^{\infty} \) is sub-additive. We also assume the following regularity condition.

Definition 2.7. A sequence \( F = \{ \log f_n \}_{n=1}^{\infty} \) of continuous functions on \( X \) is called a Bowen sequence if there exists \( M \in \mathbb{R}^+ \) such that
\[
 \sup\{ M_n : n \in \mathbb{N} \} \leq M,
\]
where
\[
 M_n = \sup \left\{ \frac{f_n(x)}{f_n(y)} : x, y \in X, x_i = y_i \text{ for } 1 \leq i \leq n \right\}.
\]
More generally, if \( M_n < \infty \) for all \( n \in \mathbb{N} \) and \( \lim_{n \to \infty} (1/n) \log M_n = 0 \), then we say that \( F \) has tempered variation. Without loss of generality, we assume \( M_n \leq M_{n+1} \) for all \( n \in \mathbb{N} \).

Remark 2.4. Definition 2.7 extends a notion introduced by Walters [W] when developing thermodynamic formalism. We say that a continuous function \( f : X \to \mathbb{R} \) belongs to the Bowen class if the sequence \( \{ \log e^{S_n(f)} \}_{n=1}^{\infty} \), where \( (S_nf)(x) = f(x) + f(\sigma(x)) + \cdots + f(\sigma^n(x)) \) for each \( x \in X \) is a Bowen sequence. The Bowen class contains the functions of summable variations and the Bowen sequences are a generalization of functions in the Bowen class (see [B2, IY1]).

We now list several assumptions we will use throughout the paper. These are hypothesis on both the system \((X, \sigma)\) and the sequence \( F \).

\begin{enumerate}(C)
\item The sequence \( F + C \) is sub-additive for some \( C \geq 0 \).
\item There exist \( p \in \mathbb{N} \) and \( D > 0 \) such that given any \( u \in B_n(X), v \in B_m(X), n, m \in \mathbb{N} \), there exists \( w \in B_k(X), 0 \leq k \leq p \) such that
\[
 \sup\{ f_{n+m+k}(x) : x \in [uvw] \} \geq D \sup\{ f_n(x) : x \in [u] \} \sup\{ f_m(x) : x \in [v] \}.
\]
\item There exists a finite set \( W \subset \bigcup_{k=0}^{p} B_k(X) \) consisting of elements \( w \) for which the property (C2) holds.
\item \( Z_1(F) := \sum_{i \in \mathbb{N}} \sup\{ f_1(x) : x \in [i] \} < \infty \).
\end{enumerate}

In addition, we consider in Section 4.2 sequences satisfying the following weaker condition.

\begin{enumerate}(D)
\item There exist \( p \in \mathbb{N} \) and a positive sequence \( \{ D_{n,m} \}_{(n,m) \in \mathbb{N} \times \mathbb{N}} \) such that given any \( u \in B_n(X), v \in B_m(X), n, m \in \mathbb{N} \), there exists \( w \in B_k(X), 0 \leq k \leq p \) such that
\[
 \sup\{ f_{n+m+k}(x) : x \in [uvw] \} \geq D_{n,m} \sup\{ f_n(x) : x \in [u] \} \sup\{ f_m(x) : x \in [v] \},
\]
where \( \lim_{n \to \infty} (1/n) \log D_{n,m} = \lim_{m \to \infty} (1/m) \log D_{n,m} = 0 \). Without loss of generality, we assume that \( D_{n,m} \geq D_{n,m+1} \) and \( D_{n,m} \geq D_{n+1,m} \).
\item There exists a finite set \( W \subset \bigcup_{k=0}^{p} B_k(X) \) consisting of elements \( w \) for which the property (D2) holds.
\end{enumerate}

If a sequence \( F \) on \( X \) satisfies (C2) ((D2), respectively) with \( w \in B_p(X) \) for all \( w \), then we say that \( F \) on \( X \) satisfies (C2) ((D2), respectively) with the strong specification.
Remark 2.5. Given a pair $u \in B_n(X), v \in B_m(X), n, m \in \mathbb{N}$, if (C2) holds when $w = \varepsilon$, then we obtain that $uv$ is an allowable word and $\sup \{ f_{n+m}(x) : x \in [uv]\} \geq D \sup \{ f_n(x) : x \in [u]\} \sup \{ f_m(x) : x \in [v]\}$. In particular, it is easy to see that if $(X, \sigma)$ is a subshift on a countable alphabet and $F$ is a Bowen sequence on $X$ satisfying (C1) and (C2), then $W = \{ \varepsilon \}$ in (C3) if and only if $(X, \sigma)$ is the full shift on a countable alphabet and $F$ is almost-additive on the full shift. The case when $F$ is an almost-additive Bowen sequence on the full shift has been studied in [Y1].

Remark 2.6. Note that if conditions (C2) or (D2) are satisfied then $(X, \sigma)$ has the weak specification property. Moreover, if conditions (C3) or (D3) are satisfied then $(X, \sigma)$ is finitely irreducible.

We can now give the definitions of pressure.

Definition 2.8. Let $(X, \sigma)$ be an irreducible subshift on a countable alphabet and $F = \{ \log\ f_n \}_{n=1}^{\infty}$ a sequence of continuous functions on $X$ with tempered variation satisfying (C1). Define $Z_n(F)$ by

$$Z_n(F) := \sum_{i_1\ldots i_n \in B_n(X)} \sup \{ f_n(x) : x \in [i_1 \ldots i_n] \}$$

and the **topological pressure** of $F$ by

$$(2.4) \quad P(F) := \limsup_{n \to \infty} \frac{1}{n} \log Z_n(F),$$

if $\limsup_{n \to \infty} (1/n) \log Z_n(F)$ exists, including possibly $\infty$ and $-\infty$.

It is clear that if $Z_1(F) < \infty$ then sub-additivity of the sequence $F + C$ implies that $P(F) = \lim_{n \to \infty} (1/n) \log Z_n(F)$ and $-\infty \leq P(F) < \infty$. We will see in Section 4 that if $Z_1(F) = \infty$, under certain additional assumptions on $(X, \sigma)$ and $F$, we obtain $P(F) = \infty$. The variational principal is studied for such sequences $F$ in Section 4.

Remark 2.7. The topological pressure in Definition 2.8 is a natural extension of the classical definition of pressure for compact subshifts. This definition was later extended by Mauldin and Urbański [MU1] for countable Markov shifts satisfying the finitely irreducible condition. This notion of pressure was also extended for sequences of regular functions defined on subshifts of finite type by Barreira [B1, B2, B3, Falconer [F1], Feng [Fe1, Fe2, Fe3] and Cao, Feng and Huang [CFH] among others. Actually, assumption (C2) was introduced by Feng [Fe3] while studying thermodynamic formalism for potentials related to product of matrices and appeared also in the study of dimension of non-conformal repellers [Fe4, Y1]. Moreover, when $(X, \sigma)$ is a subshift on a finite alphabet, Feng [Fe4] studied thermodynamic formalism for the class of sequences which satisfies (C1) and (C2) (see Theorem 5.2). Note that in this case (C3) and (C4) are automatically satisfied by compactness. Käenmäki and Reeve [KR] extended the work of Feng [Fe3, Fe4] to the full shift on a countable alphabet. They studied thermodynamic formalism for sequences of potentials defined on the full shift satisfying what they called *quasi multiplicative* property. This assumption on the sequences used in [KR] is equivalent to assume conditions (C1), (C2) with $w \in \bigcup_{k=1}^p B_k(X)$, and (C3) with $W \subset \bigcup_{k=1}^p B_k(X)$ on a Bowen sequence on the full shift. In Section 3.1, we discuss the differences between almost-additivity and conditions (C2) and (D2).

Next we define the Gurevich pressure. Throughout the paper, we identify the set of a countable alphabet with $\mathbb{N}$.

Definition 2.9. Let $(X, \sigma)$ be an irreducible subshift on a countable alphabet and $F = \{ \log\ f_n \}_{n=1}^{\infty}$ a sequence of continuous functions on $X$ with tempered variation satisfying (C1) and (D2). For $a \in \mathbb{N}$, define

$$Z_n(F, a) := \sum_{x : \sigma^n x = x} f_n(x) \chi_{[a]}(x),$$
where \( \chi_{\{a\}}(x) \) is a characteristic function of the cylinder \([a]\). The Gurevich pressure of \( \mathcal{F} \) on \( X \), denoted by \( P_G(\mathcal{F}) \), is defined by

\[
P_G(\mathcal{F}) := \limsup_{n \to \infty} \frac{1}{n} \log Z_n(\mathcal{F}, a),
\]

if \( \limsup_{n \to \infty} (1/n) \log Z_n(\mathcal{F}, a) \) is independent of \( a \in \mathbb{N} \).

In Proposition 2.1, we will study the definition of Gurevich pressure \( P_G(\mathcal{F}) \) when \((X, \sigma)\) is a countable Markov shift and \( Z_1(\mathcal{F}) < \infty \). If \( Z_1(\mathcal{F}) = \infty \), under certain assumptions on \((X, \sigma)\) and \( \mathcal{F} \), we obtain \( P(\mathcal{F}) = P_G(\mathcal{F}) = \infty \) (see Section 4). The definition is also studied in Section 4.2 when \((X, \sigma)\) is a finitely irreducible countable sofic shift.

**Remark 2.8.** The Gurevich entropy was first introduced by Gurevich for countable Markov shifts. This notion was later extended by Sarig [S1] where he defines the Gurevich pressure of regular potentials defined on topologically mixing countable Markov shifts. In [FFY, Section 1], the definition was extended to a certain type of irreducible countable Markov shift. It was shown by Dougal and Sharp in [DS, Section 3] that the definition could be extended to topological transitive shifts on countable alphabets for regular potentials. In all these cases, it was shown that the definition does not depend on the symbol \( a \) chosen. The Gurevich pressure was defined and studied for almost-additive sequences on topologically mixing countable Markov shifts by Iommi and Yayama [Y1]. We stress that the definition given here extends both the class of sequences of potentials and the class of shifts (satisfying the weak specification) previously considered in the literature.

It was shown by Mauldin and Urbański [MU2] and by Sarig [S3] that when restricted to topologically mixing countable Markov shifts satisfying the BIP property for a regular potential, Definitions 2.8 and 2.9 coincide. The next result extends this observation to countable Markov shifts satisfying the weak specification property and to sequences of functions satisfying mild additivity assumptions.

**Proposition 2.1.** Let \((X, \sigma)\) be a countable Markov shift and \( \mathcal{F} = \{\log f_n\}_{n=1}^\infty \) a sequence on \( X \) with tempered variation satisfying (C1) and (D2). If \( P(\mathcal{F}) < \infty \), then

\[
P(\mathcal{F}) = P_G(\mathcal{F}).
\]

If \( \mathcal{F} \) satisfies (D2) with the strong specification, then \( \limsup \) in (2.5) can be replaced by \( \lim \).

**Proof.** First we observe that \( P(\mathcal{F}) < \infty \) if and only if \( Z_1(\mathcal{F}) < \infty \) (see Proposition 4.2). Let \( a \in \mathbb{N} \) be fixed and \( c_n := x_1 \ldots x_n \in B_n(X) \). By assumption (D2) there exist allowable words \( w_1, w_2 \) with \( 0 \leq |w_1|, |w_2| \leq p \), such that \( aw_1x_1 \ldots x_\zeta w2a \) is an allowable word of length \( n + 2 + |w_1| + |w_2| \) satisfying

\[
\sup \{f_{n+2+|w_1|+|w_2|}(x) : x \in [aw_1c_nw_2a]\} \\
\geq D_{1,n}D_{1+p+n,1} \sup \{f_n(x) : x \in [c_n]\}(\sup \{f_1(x) : x \in [a]\})^2.
\]

Since \( \mathcal{F} \) has tempered variation, for any \( x \in [aw_1c_nw_2a] \) we have that

\[
\sup \{f_{n+2+|w_1|+|w_2|}(x) : x \in [aw_1c_nw_2a]\} \\
\leq M_{n+2+2f_{n+2+|w_1|+|w_2|}}(x) \leq M_{n+2+2f_{n+1+|w_1|+|w_2|}}(x) \sup \{f_1(x) : x \in [a]\} e^C.
\]

Since \( \tilde{x} = (aw_1c_nw_2)^\infty = (aw_1c_nw_2aw_1c_nw_2aw_1c_nw_2 \ldots) \) is a periodic point with period \( n + |w_1| + |w_2| + 1 \), we obtain

\[
f_{n+|w_1|+|w_2|+1}(\tilde{x}) \geq \frac{D_{1,n}D_{1+p+n,1}e^{-C}}{M_{n+2p+2}} \sup \{f_n(x) : x \in [c_n]\} \sup \{f_1(x) : x \in [a]\}.
\]
Remark that since $\mathcal{F}$ has tempered variation we have that $\sup\{f_1(x) : x \in [a]\}$ is bounded. Setting $d_n = (D_{1,n}D_{1+p+n,1}\sup\{f_1(x) : x \in [a]\})/(e^CM_{n+2p+2})$ and summing over all allowable words $c_n = x_1 \ldots x_n \in B_n(X)$, we obtain

$$\sum_{i=n+1}^{n+2p+1} Z_n(\mathcal{F}, a) \geq d_n Z_n(\mathcal{F}) > 0. \tag{2.7}$$

Hence, there exists $n + 1 \leq i_n \leq n + 2p + 1$ such that $Z_{i_n}(\mathcal{F}, a) \geq (d_nZ_n(\mathcal{F}))/(2p + 1)$. Therefore,

$$\frac{1}{i_n} \log Z_{i_n}(\mathcal{F}, a) \geq \frac{1}{n + 2p + 1} \left( \log \frac{1}{2p + 1} + \log d_n + \log Z_n(\mathcal{F}) \right).$$

Thus

$$\limsup_{n \to \infty} \frac{1}{i_n} \log Z_{i_n}(\mathcal{F}, a) \geq P(\mathcal{F}). \tag{2.8}$$

Since $Z_{i_n}(\mathcal{F}, a) \leq Z_{i_n}(\mathcal{F})$ for all $i_n$ and $a$ is arbitrary, (2.8) implies (2.6).

Next we show the second part. If $\mathcal{F}$ satisfies (D2) with the strong specification, we obtain for all $n \in \mathbb{N}$

$$Z_{n+2p+1}(\mathcal{F}, a) \geq d_n Z_n(\mathcal{F}) > 0.$$

Thus similar arguments above imply that

$$\limsup_{n \to \infty} \frac{1}{n} \log Z_n(\mathcal{F}, a) = \liminf_{n \to \infty} \frac{1}{n} \log Z_n(\mathcal{F}, a).$$

In particular one can take a limit instead of a limsup in the definition of Gurevich pressure. \hfill \square

**Remark 2.9.** In Section 4, we obtain (2.6) when $Z(\mathcal{F}) = \infty$ under certain assumptions on $(X, \sigma)$ and $\mathcal{F}$. In Section 4.2, for a sequence $\mathcal{F}$ on a finitely irreducible countable sofic shift we establish conditions ensuring $P(\mathcal{F}) = P_G(\mathcal{F})$.

**Remark 2.10 (Entropy).** A particular case of the definitions considered in Section 2.2 is when the sequence $\mathcal{F} = \{\log f_n\}_{n=1}^\infty$ is such that for every $n \in \mathbb{N}$ we have that $f_n = 0$. In this case we denote $\mathcal{F} = 0$. The numbers $P(0)$ and $P_G(0)$ are called the entropy and the Gurevich entropy respectively. It is well known that for a compact irreducible sofic shift (see Definition 2.11) both notions coincide (see [LM, Theorem 4.3.6]). However, even for topologically mixing countable Markov shifts these two notions can be different, we can have $P_G(0) < P(0)$. In Proposition 2.1, fairly general conditions are obtained so that we can still have an equality $P(0) = P_G(0)$ in the non-compact setting. We use the following notation $P(0) = h(\sigma)$ and $P_G(0) = h_G(\sigma)$.

### 2.3. Factor maps

The goal of this section is to study certain subshifts which are images of countable Markov shifts under factor maps. The following class of maps will play an important role in this article.

**Definition 2.10.** Let $(X, \sigma_X)$ and $(Y, \sigma_Y)$ be subshifts on countable alphabets. A one-block code is a map $\pi : X \to Y$ for which there exists a function, denoted again by $\pi$, $\pi : B_1(X) \to B_1(Y)$ such that $(\pi(x)_i) = \pi(x_i)$ for all $i \in \mathbb{N}$. For $u = x_1 \ldots x_k \in B_k(X), \ k \in \mathbb{N}$, we denote $\pi(x_1) \ldots \pi(x_k) \in B_k(Y)$ by $\pi(u)$. A map $\pi : X \to Y$ is a factor map if it is continuous, surjective and satisfies $\pi \circ \sigma_X = \sigma_Y \circ \pi$. For a one-block factor map $\pi : X \to Y$ where $X$ is an irreducible countable Markov shift, let $v \in B_k(Y)$. We denote by $\pi^{-1}(v)$ the set of allowable words $u$ of length $k$ of $X$ such that $\pi(u) = v$ and by $|\pi^{-1}(v)|$ the cardinality of the set. Throughout the paper, we only consider one-block factor maps $\pi : X \to Y$ such that $|\pi^{-1}(i)| < \infty$ for any $i \in \mathbb{N}$. Hence for each $k \in \mathbb{N}$, $v \in B_k(Y)$, we have $|\pi^{-1}(v)| < \infty$. 
Lemma 2.2. Let \((X, \sigma_X)\) be a subshift on a countable alphabet and \((\Sigma, \sigma)\) the full shift on a countable alphabet. Let \(\pi : X \to \Sigma\) be a one-block code such that \(|\pi^{-1}(i)| < \infty\) for each \(i \in \mathbb{N}\). Let \(Y := \pi(X)\). Then \((Y, \sigma_Y)\) is a subshift on a countable alphabet.

Proof. It is easy to see that \(Y\) is invariant and we show that \(Y\) is closed. For \(m \in \mathbb{N}\), let \(y^{(m)} = \{y^{(m)}_n\}_{n=1}^\infty \in Y\). Let \(\{y^{(m)}_n\}_{m=1}^\infty\) be a sequence in \(Y\) converging to \(y = \{y_i\}_{i=1}^\infty\). We show that \(y \in Y\). Since \(Y\) is the image of \(X\) under \(\pi\), for each \(m \in \mathbb{N}\), we can pick an \(x^{(m)} \in X\) such that \(\pi(x^{(m)}) = y^{(m)}\) and \(x^{(m)} = \{x^{(m)}_n\}_{n=1}^\infty\). Fix \(l \in \mathbb{N}\). Since \(\{y^{(m)}_n\}_{m=1}^\infty\) converges to \(y \in Y\), there exists \(M \in \mathbb{N}\) such that \(d(y^{(m)}_n, y) < 1/2^l\) for all \(m \geq M\). Then we have \(y^{(m)}_i = y_i\) for all \(m \geq M, 1 \leq i \leq l + 1\). Note that \(\pi^{-1}(y^{(M)}_i)\) is a finite set for each \(1 \leq i \leq l + 1\). Consider the sequence \(\{x^{(m)}_n\}_{m=M}^\infty\). Then we have \(x_i^{(m)} \in \pi^{-1}(y^{(M)}_i)\) for \(1 \leq i \leq l + 1, m \geq M\). Since there are finitely many symbols in \(\pi^{-1}(y^{(M)}_i)\), there exists \(x_i \in \pi^{-1}(y^{(M)}_i)\) such that \(x_i\) is the initial symbol of \(x^{(m)}_i\), for infinitely many \(m \geq M\). Now we extract a subsequence \(\{x^{(m)}_{i,n}\}_{m=M}^\infty\) of sequences with the initial symbol \(x_i\) from \(\{x^{(m)}_{i,n}\}_{m=M}^\infty\). Define \(\{x^{(m)}_{i,n}\}_{n=1}^\infty := \{x^{(m)}_{i,n}\}_{m=M}^\infty\). Repeating this process, for each \(1 \leq i \leq l + 1\), there exists \(x_i \in \pi^{-1}(y^{(M)}_i)\) and a sequence \(\{x^{(m)}_{i,n}\}_{n=1}^\infty\) of sequences with the \(i\) th symbol \(x_i\) such that \(\{x^{(m)}_{i,n}\}_{n=1}^\infty\) is a subsequence of \(\{x^{(i-n,1)}_{i,n}\}_{n=1}^\infty\). We define \(x_i^*\) for \(i = 1, 2, \ldots, 2\) similarly. Given \(l + 1\), there exists \(M_1\) such that \(d(y^{(m)}_i, y) < 1/2^{l+i+1}\) for all \(m \geq M_1\). Then we have \(y^{(m)}_i = y_i\) for all \(m \geq M_1, 1 \leq i \leq l + 2\). Consider the sequence \(\{x^{(l+1,n)}_{i,n}\}_{n=1}^\infty := \{x^{(l+1,n)}_{i,n}\}_{n=1}^\infty \cap \{x^{(m)}_{i,n}\}_{m=M_1}^\infty\). Since there are finitely many symbols in \(\pi^{-1}(y^{(M_1)}_i)\), there exists \(x_{l+2} \in \pi^{-1}(y^{(M_1)}_{l+2})\) such that \(x_{l+2}\) is the \((2 + l)\) th symbol of \(\{x^{(l+1,n)}_{i,n}\}_{n=1}^\infty\) for infinitely many \(n\). Now we extract a subsequence \(\{x^{(l+2,n)}_{i,n}\}_{n=1}^\infty\) of sequences with the \((2 + l)\) th symbol \(x_{l+2}\) from \(\{x^{(l+1,n)}_{i,n}\}_{n=1}^\infty\). Since \(\pi^{-1}(k) \leq 2^{2l+1}\) for each \(k \in \mathbb{N}\), by repeating this process, for each \(i \geq 2\) there exist \(x_{l+i} \in \pi^{-1}(y_{l+i})\) and a sequence \(\{x^{(l+i+1,n)}_{i,n}\}_{n=1}^\infty\). With the \(i\) th symbol \(x_i^*\), each of which is a subsequence of \(\{x^{(l+i-1,n)}_{i,n}\}_{n=1}^\infty\). Define \(x^* = \{x_i^*\}_{i=1}^\infty\). By a diagonal argument, it is clear that the sequence \(\{x^{(l+i+1,n)}_{i,n}\}_{n=1}^\infty\) converges to \(x^*\). Since \(X\) is closed, we obtain that \(x^* \in X\). Then \(\pi(x^*) = \{\pi(x_i^*)\}_{i=1}^\infty = \{y_i\}_{i=1}^\infty = y\). Hence \(Y\) is closed.

In Lemma 2.2, if \(X\) is a countable Markov shift, then \(\pi : X \to Y\) is a one-block factor map. Hence we find a class of subshifts which generalize countable Markov shifts. Recall that if \((X, \sigma)\) is a finite state Markov shift, then the image of \(X\) under a one-block factor map is a sofic shift [LM, BP]. In the following, we generalize this definition to the case when \((X, \sigma)\) is a countable Markov shift.

Definition 2.11. A countable sofic shift is a subshift on a countable alphabet which is the image of a countable Markov shift under a one-block factor map \(\pi\) such that \(|\pi^{-1}(i)| < \infty\) for each \(i \in \mathbb{N}\). In particular, an irreducible countable sofic shift is the image of an irreducible countable Markov shift.

Remark 2.11. Note that an irreducible subshift is defined in Definition 2.1. In Definition 2.11, in order for \(Y\) to be an irreducible countable sofic shift, we additionally assume that it is an image of an irreducible countable Markov shift.

It is well known that if \(X\) and \(Y\) are subshifts on finite alphabets such that there exists a factor map \(\pi : X \to Y\), then \(h(X) \geq h(Y)\). In the non-compact case, this is in general not true (see the discussion in [LM, Section 13.9]). However, the next lemma shows that under suitable assumptions this property still holds.

Lemma 2.3. Let \((X, \sigma_X)\) and \((Y, \sigma_Y)\) be topologically mixing countable Markov shifts and \(\pi : X \to Y\) a one-block factor map such that \(|\pi^{-1}(n)| < \infty\) for each \(n \in \mathbb{N}\). Then \(h(\sigma_X) \geq h(\sigma_Y)\).
Proof. Recall that the Gurevich entropy satisfies the following approximation property by compact sets [Gu1, Gu2]

\[ h_G(\sigma_X) = \sup \{ h(\sigma_X|_K) : K \subset X \text{ compact and invariant} \} \]

\[ = \sup \{ h(\sigma_X|_{\Sigma_K}) : \Sigma_K \subset X \text{ topologically mixing finite Markov shift} \}. \]

Since for every \( n \in \mathbb{N} \), we have that \(|\pi^{-1}(n)| < \infty\), for every \( \Sigma_K \subset Y \) topologically mixing finite Markov shift we have that \( \pi^{-1}(\Sigma_K) \) is a compact subshift of \( X \). Therefore, by [Kit, Proposition 4.16] we have that

\[ h_G(\sigma_X|_{\pi^{-1}(\Sigma_K)}) \geq h_G(\sigma_X|_{\Sigma_K}). \]

The result now follows. □

3. Examples

In this section, we study the types of sequences introduced in 2.2 and present some examples.

3.1. Differences between the (C2) condition and almost-additivity. This section is devoted to study the relations and differences between the additivity assumptions we have considered. That is, we establish relations between almost-additivity and conditions (C2) and (D2) introduced in Section 2.2. The results depend upon the combinatorial structure of the shifts.

Remark 3.1. If \((X, \sigma)\) is an irreducible Markov shift defined on a finite alphabet sequence on \( X \), then any almost-additive Bowen sequence satisfies condition (C2).

Next lemma shows that the result in Remark 3.1 also holds for a finitely irreducible subshift on a countable alphabet. Even more, under weaker regularity assumptions it is possible to prove that an almost-additive sequence satisfies condition (D2).

Lemma 3.1. Let \((X, \sigma)\) be a finitely irreducible subshift on a countable alphabet and \( \mathcal{G} = \{ \log g_n \}_{n=1}^{\infty} \) an almost-additive sequence on \( X \) with tempered variation. Then \( \mathcal{G} \) satisfies (C1), (D2) and (D3). If \( \mathcal{G} \) is an almost-additive Bowen sequence on \( X \), then it satisfies (C1), (C2) and (C3).

Proof. Since \((X, \sigma)\) is a finitely irreducible subshift on a countable alphabet, there exist \( p \in \mathbb{N} \) and a finite set \( W_1 \subset \bigcup_{n=0}^{p-1} B_1(X) \) such that for any \( n, m \in \mathbb{N} \) and \( u \in B_n(X), v \in B_m(X) \) there exists \( w \in W_1 \) such that \( uwv \) is an allowable word. Since \( W_1 \) is a finite set and \( \mathcal{G} \) has tempered variation, there exists \( Q_1 > 0 \) such that

\[ \sup_{w \in W_1, |w| \geq 1} \{ g_{[w]}(y) : y \in [w] \} > Q_1. \]

For \( n \in \mathbb{N} \), let \( M_n \) be defined as in Definition 2.7. Let \( x \in [uwv] \), where \( |w| = k \geq 1 \). Then

\begin{equation}
(3.1) \quad g_{n+m+k}(x) \geq e^{-C} g_n(x) g_k(\sigma^n x) g_m(\sigma^{k+n} x) \geq \frac{e^{-C} Q_1}{M_p} g_n(x) g_m(\sigma^{k+n} x). 
\end{equation}

Now consider a pair \( u \in B_n(X), v \in B_m(X) \) such that \( uw \) is an allowable word. If \( x \in [uw] \), then we obtain \( g_{n+m+k}(x) \geq e^{-C} g_n(x) g_m(\sigma^n x) \). Let \( Q = \min\{Q_1, 1\} \). Then (D2) holds in particular for \( p \) equal to the same \( p \) that appears in the specification property and we obtain the result by setting \( D_{n,m} = (e^{-C} Q)/(M_p M_n M_m) \) in (D2) and \( W = W_1 \) in (D3). If the sequence \( \mathcal{G} \) is an almost-additive Bowen sequence, the same argument replacing \( M_p, M_n \) and \( M_m \) by \( M \) yields the desired result. □

Lemma 3.2. Let \((X, \sigma)\) be a subshift on a countable alphabet, \( \mathcal{G} = \{ \log g_n \}_{n=1}^{\infty} \) an almost-additive sequence on \( X \) with tempered variation, and \( F = \{ \log f_n \}_{n=1}^{\infty} \) a sequence on \( X \) satisfying (C1), (D2) and (D3). Define \( \mathcal{H} = \{ \log(f_n/g_n) \}_{n=1}^{\infty} \). Then \( \mathcal{H} \) satisfies (C1), (D2) and (D3).

Proof. The proof is straightforward. We use the similar approach as in Lemma 3.1. □
Example 3.1. A continuous function on a finitely irreducible subshift with tempered variation. In this example, we show that the formalism developed in this article generalizes results concerning continuous potentials satisfying mild regularity assumptions. Let \( f \) be a continuous function defined on a finitely irreducible subshift \( X \). Denote by

\[
A_n := \sup \{|(S_n f)(x) - (S_n f)(y)| : x_i = y_i, 1 \leq i \leq n\}.
\]

We say that \( f \) has tempered variation if \( A_n < \infty \) for all \( n \in \mathbb{N} \) and \( \lim_{n \to \infty} \frac{1}{n} A_n = 0 \). We remark that sometimes (see for example [ooY]) the definition of tempered variation is given without the finiteness assumption \( A_n < \infty \). We stress that in this paper we always do assume finiteness.

Let \( f \) be a continuous function on a finitely irreducible subshift \( X \) with tempered variation. Following the procedure described in Remark 2.4, for each \( n \in \mathbb{N} \), define \( f_n(x) = e^{(S_n f)(x)} \) and \( \mathcal{F} = \{\log f_n\}_{n=1}^{\infty} \). The sequence \( \mathcal{F} \) is additive. Moreover, by Lemma 3.1, \( \mathcal{F} \) satisfies (D2) and (D3).

Example 3.2. An almost-additive sequence on a countable Markov shift which does not satisfy (C2). Let \( A \) be a transition matrix on a countable alphabet defined by

\[
A = \begin{pmatrix}
1 & 0 & 0 & 1 & 0 & 0 & 1 & \ldots \\
0 & 1 & 1 & 1 & 0 & 0 & 0 & \ldots \\
0 & 1 & 1 & 1 & 0 & 0 & 0 & \ldots \\
1 & 1 & 1 & 1 & 0 & 0 & 0 & \ldots \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & \ldots \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & \ldots \\
1 & 0 & 0 & 0 & 1 & 1 & 1 & \ldots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}
\]

and consider the countable Markov shift \((X, \sigma)\) determined by \( A \) (see Figure 1). Let \( \{\lambda_n\}_{n=1}^{\infty} \) be a sequence of real numbers such that \( \lambda_n \in (0, 1) \) and \( \sum_{j=1}^{\infty} \lambda_j < \infty \). Let \( \{\log c_n\}_{n=1}^{\infty} \) be an almost-additive sequence of real numbers, that is, there exists a constant \( C > 0 \) such that

\[
e^{-C} c_n c_m \leq c_{n+m} \leq e^C c_n c_m.
\]

For \( n \in \mathbb{N} \), define \( g_n : \Sigma \to \mathbb{R} \) by

\[
g_n(x) = c_{n} \lambda_{i_1} \lambda_{i_2} \cdots \lambda_{i_n}, \text{ for } x \in [i_1 \ldots i_n],
\]

and let \( \mathcal{G} = \{\log g_n\}_{n=1}^{\infty} \). These sequences have been studied in [Y1, Example 1] when defined on the full shift.

![Figure 1. The graph defining X in Example 3.2](image)

Lemma 3.3. The sequence \( \mathcal{G} = \{\log g_n\}_{n=1}^{\infty} \) defined on \( X \) is an almost-additive Bowen sequence. However, it does not satisfy (C2).
Proof. It is clear that $G$ is an almost-additive Bowen sequence. Observe that $(X, \sigma)$ is topologically mixing and that $3$ is a strong specification number and, moreover, $X$ is not finitely irreducible.

Claim 3.1. Let $(X, \sigma)$ be a subshift on a countable alphabet and $F = \{\log f_n\}_{n=1}^\infty$ a Bowen sequence on $X$ satisfying (C1) and (C2). Let $w \in \bigcup_{i=1}^p B_i(X)$ be an allowable word from (C2). Then there exists $C' > 0$ such that for any $w$ of length $k$, we have $\sup\{f_k(x) : x \in [w]\} \geq C'$.

Proof. Since (C2) is satisfied, given $u \in B_n(X), v \in B_m(X)$, there exist $0 \leq k \leq p$ and $w = w_1 \ldots w_k \in B_k(X)$ with the property

$$\sup\{f_{n+m+k}(x) : x \in [uv]\} \geq D\sup\{f_n(x) : x \in [u]\}\sup\{f_m(x) : x \in [v]\}. \quad (3.2)$$

We consider only $uvw$ with the length $k$ of $w \geq 1$. For any $x \in [uvw]$, it is a consequence of (3.2), (C1) and the Bowen property of $F$ that

$$Me^{2C}f_n(x)f_k(\sigma^n x)f_m(\sigma^{k+n} x) \geq Df_n(x)f_m(\sigma^{k+n} x).$$

Hence

$$\sup\{f_k(x) : x \in [w]\} \geq \frac{D}{Me^{2C}} = C'.$$

Assume by way of contradiction that the sequence $G$ satisfies (C2) for some $p \in \mathbb{N}$. Consider the symbol 3 and 3n for some $n \in \mathbb{N}$. To connect 3 and 3n, the symbol $3n+1$ must be passed through. Suppose $w = w_1 \ldots w_k$ is a word of length $k \leq p$ such that $3w(3n)$ is allowable and satisfies (C2). Then $3n+1$ must appear in some $w_i, 1 \leq i \leq k$. Clearly $k \geq 1$. Since $\lambda_j$ is bounded above by some constant $C'' > 1$ for all $j \in \mathbb{N}$, we obtain

$$\sup\{g_k(x) : x \in [w]\} \leq \max_{1 \leq k \leq p} \{c_p\}C''^{n-1}\lambda_{3n+1}.$$ 

Applying Claim 3.1, $\lambda_{3n+1}$ is bounded above by a constant for all $n \in \mathbb{N}$. However by the construction of $\lambda_j$, $\lim_{n \to \infty} \lambda_{3n+1} = 0$. This contradiction proves the lemma. \hfill $\square$

Example 3.3. A sequence satisfying (C1),(C2) and (C3). In this example, we will make use of the notion of factor map (see Section 2.3). Let $(X, \sigma_X), (Y, \sigma_Y)$ be subshifts on countable alphabets, and $\pi : X \to Y$ a one-block factor map such that $|\pi^{-1}(i)| < \infty$, for every $i \in \mathbb{N}$. Define $\phi_n : Y \to \mathbb{R}$ by $\phi_n(y) = \log |\pi^{-1}(y_1 \ldots y_n)|$ and $\Phi = \{\log \phi_n\}_{n=1}^\infty$. Then $\Phi$ is a Bowen sequence. In the next lemma, we prove that under suitable assumptions on $X$ and $Y$ the sequence $\Phi$ satisfies (C1), (C2) and (C3). Let $\varepsilon_X$ and $\varepsilon_Y$ be the empty words of $X$ and $Y$ respectively. By convention, let $\pi(\varepsilon_X) = \varepsilon_Y$.

Lemma 3.4. Let $(X, \sigma_X)$ be a countable Markov shift, $(Y, \sigma_Y)$ a subshift on a countable alphabet, and $\pi : X \to Y$ a one-block factor map such that $|\pi^{-1}(i)| < \infty$ for each $i \in \mathbb{N}$. If $X$ is finitely irreducible, then $\Phi = \{\log \phi_n\}_{n=1}^\infty$ is a Bowen sequence on $Y$ satisfying (C1),(C2) and (C3). If $W_1$ is a finite set from Definition 2.3, then let $\pi(W_1) = \{\pi(w) : w \in W_1\}$. For any $u \in B_n(Y), v \in B_m(Y), n, m \in \mathbb{N}$, there exists $w' \in \pi(W_1)$ such that $|\pi^{-1}(uvw')| \geq (1/|W_1||\pi^{-1}(u)||\pi^{-1}(v)|).$

Proof. See [Fe4, Lemma 5.7] in which the above result was studied for the case when $X$ is an irreducible subshift on finite alphabets. This implies the result. \hfill $\square$

Remark 3.2. The case when $X$ is not finitely irreducible is studied in Example 3.8 in which $\Phi$ on $Y$ does not satisfy (C3). We also remark that in general $\Phi$ is not almost-additive (see [Y1, Y2]).
3.2. Examples of sequences on irreducible countable sofic shifts. We provide a wide range of examples of sequences of functions satisfying (or not) different additivity properties. Some of these examples can only occur in non-compact settings and show some of the new phenomena that have to be considered in the countable alphabet situation. The examples in this section come from a construction in the theory of factor maps and will also appear in the following sections when we study the variational principle. Let \( \Phi \) be the sequence of functions as in Example 3.3.

Example 3.4. A sequence on a finitely irreducible countable Markov shift satisfying (C1), (C2) and (C3). In this example, we construct a sequence of functions which satisfies (C1), (C2) and (C3), but fails to be almost-additive. Let \( (X, \sigma) \) be a countable Markov shift determined by the transitions given by Figure 2.

Let \( \pi : \mathbb{N} \to \mathbb{N} \) be the function defined by \( \pi(-i + n(n + 1)/2) = n, \ i = 0, \ldots, n - 1 \) for \( n \in \mathbb{N} \) and \( \Sigma \) be the full shift on a countable alphabet. Define \( \pi : X \to \Sigma \) by \((\pi(x))_i = \pi(x_i)\) for all \( i \in \mathbb{N} \) and denote \( \pi(X) \) by \( Y \). Then the map \( \pi : X \to Y \) is a one-block factor map. Note that since \( |\pi^{-1}(i)| = i \) for \( i \in \mathbb{N} \) we have that \( |\pi^{-1}(i)| \) is not uniformly bounded. We stress that this property cannot occur when \( X \) is a finite state Markov shift. \( X \) has a strong specification number equal to 2, just by considering \( W = \{12, 22\} \). Thus, the countable Markov shift \( Y \) also has a strong specification number 2.

We first observe that \( \Phi \) is not almost-additive on \( Y \). Let \( A \) be the transition matrix for \( X \). It was shown in [Y1, Example 5.6] that \( \Phi \) is not almost-additive on \( \pi(X_{A([1,2,3] \times [1,2,3])}) \). Let \( k \geq 3 \) be fixed and define

\[
\psi_n(y) = \frac{\phi_n(y)}{(|\pi^{-1}(y_1)| \cdots |\pi^{-1}(y_n)|)^k},
\]

and \( \Psi = \{\log \psi_n\}_{n=1}^\infty \). The sequence \( \Psi \) is not almost-additive but it is sub-additive. By Lemma 3.4, condition (C2) holds with \( p = 2 \). For \( u \in B_n(Y) \) and \( v \in B_m(Y) \), there exists a word \( w \in \{\pi(12), \pi(22)\} \) of length 2 such that

\[
\sup\{\psi_{n+m+2}(y) : y \in [uvw]\} \geq \frac{1}{2^{2k+1}} \cdot \sup\{\psi_n(y) : y \in [u]\} \sup\{\psi_m(y) : y \in [v]\}.
\]

Hence \( \Psi \) is a Bowen sequence on \( Y \) satisfying (C1), (C2) and (C3).

![Figure 2. The graph defining X in Example 3.4](image-url)

Example 3.5. A sequence on a finitely irreducible countable sofic shift satisfying (C1), (C2) and (C3). We study a general case of Example 3.4. Let \( (X, \sigma_X) \) be a finitely irreducible countable Markov shift, \( (Y, \sigma_Y) \) a subshift, and \( \pi : X \to Y \) be a one-block factor map. Thus, \( (Y, \sigma_Y) \) is a finitely irreducible countable sofic shift. Suppose there exist \( C_1, C_2 > 0, k \geq 1 \) such that for every \( i \in \mathbb{N} \) we have

\[
C_1 i^k \leq |\pi^{-1}(i)| \leq C_2 i^k.
\]

For \( y \in [y_1 \ldots y_n] \), define

\[
\psi_n(y) := \frac{\phi_n(y)}{(|\pi^{-1}(y_1)| \cdots |\pi^{-1}(y_n)|)^k+2}.
\]
and \( \Psi = \{ \log \psi_n \}_{n=1}^\infty \). By Lemmas 3.2 and 3.4, the sequence \( \Psi \) is a sub-additive Bowen sequence on \( Y \) satisfying (C1), (C2) and (C3).

**Example 3.6. A sequence on a finitely irreducible countable sofic shift satisfying (C1), (C2) and (C3).** Let \((X, \sigma_X)\) be a finitely irreducible countable Markov shift, \((Y, \sigma_Y)\) a subshift, and \( \pi : X \to Y \) be a one-block factor map such that \( |\pi^{-1}(i)| < \infty \) for any \( i \in \mathbb{N} \). Thus, \((Y, \sigma_Y)\) is a finitely irreducible countable sofic shift. Let \( K > 0 \). For \( y \in \{ y_1 \ldots y_n \} \), we define

\[
\psi_n(y) = \frac{\phi_n(y)}{K^{y_1 + \cdots + y_n}}
\]

and let \( \Psi = \{ \log \psi_n \}_{n=1}^\infty \). Then \( \Psi \) is a sub-additive Bowen sequence on \( Y \) satisfying (C1), (C2) and (C3).

**Example 3.7. A sequence on a finitely irreducible countable sofic shift satisfying (C1), (C2) and (C3).** Let \( \mathcal{G} \) be defined as in Theorem 6.1 in Section 6. Then \( \mathcal{G} \) is a Bowen sequence defined on a finitely irreducible countable sofic shift satisfying (C1), (C2) and (C3).

**Example 3.8. A sequence satisfying (C1) and (C2) but not (C3).** Here we present an example of a sequence which satisfies (C1) and (C2), but fails to be almost-additive and for which the finiteness condition (C3) does not hold. We consider a factor map defined on a countable Markov shift which is not finitely irreducible. Let \((X, \sigma)\) be the countable Markov shift determined by the transitions given by Figure 3. We partition the alphabet defining \( X \) in the following way: \( F_1 = \{ 1 \}, F_2 = \{ 2, 3 \}, F_3 = \{ 4, 5, 6 \} \ldots \), in general \( F_n \) consists of \( n \) symbols, such that the subshift of \( X \) restricted to the symbols of \( F_n \) is the full shift on \( n \) symbols. Let \( \pi : \mathbb{N} \to \mathbb{N} \) be the function defined by \( \pi(a) = n \) if \( a \in F_n, n \in \mathbb{N} \) and let \( \Sigma \) be the full shift on a countable alphabet. Define \( \pi : X \to \Sigma \) by \( (\pi(x))_i = \pi(x_i) \) for all \( i \in \mathbb{N} \). Then \( Y = \pi(X) \). Then \( Y \) is a countable Markov shift and \( \pi : X \to Y \) is a one-block factor map. Note that \( X \) is not finitely irreducible and that 3 is a specification number for \( X \). On the other hand, \( Y \) is finitely primitive with a specification number 1. Noting that \( |\pi^{-1}(i)| = i \) and \( |\pi^{-1}(1)| = 1 \), \( |\pi^{-1}(1)|/|\pi^{-1}(i)| = 1 \) is not bounded below by a constant. Therefore the sequence \( \Phi = \{ \log \phi_n \}_{n=1}^\infty \) is not almost-additive, however it is sub-additive by construction. Let \( u = u_1 \ldots u_n \in B_n(Y) \) and \( v = v_1 \ldots v_m \in B_m(Y) \). We claim that

\[
|\pi^{-1}(u_{n+1}v)| \geq |\pi^{-1}(u)||\pi^{-1}(v)|
\]

and hence (C2) is satisfied. To see this, consider a preimage \( \bar{u} = \bar{u}_1 \ldots \bar{u}_n \) of \( u \) and \( \bar{v} = \bar{v}_1 \ldots \bar{v}_m \) of \( v \). Then \( \bar{u}_n \in F_s \) and \( \bar{v}_1 \in F_t \) for some \( s, t \in \mathbb{N} \). Assume \( s \neq 1 \) and \( t \neq 1 \). Define \( a_s \in F_s \) and \( a_t \in F_t \) such that \( 1a_s1 \) and \( 1a_t1 \) are allowable words. Then \( \bar{u}_n1a_s1v \) is an allowable word of \( X \) and \( \pi(\bar{u}_n1a_s1v) = u_{n+1}v \). Similar arguments when \( s = 1 \) or \( t = 1 \) yield the same result. The claim now follows, indeed \( \Phi \) is a sub-additive Bowen sequence on \( Y \) satisfying (C2) with the strong specification. However, (C3) is not satisfied. If we let \( W \) be the set consisting of all possible \( u_{n+1}v \) in (3.3), then \( W = \{ i \mid i : j, j \in \mathbb{N} \} \).

We observe that for any \( p \in \mathbb{N} \) (C3) is not satisfied. Suppose \( F \) satisfies (C2) and (C3) and let \( W \) be a finite set as in (C3). Clearly \( W \neq \{ \varepsilon \} \). Observe that such a finite set \( W \) consists of allowable words \( w \) of the following four types. If \( w = w_1 \ldots w_k \), for \( 1 \leq k \leq p \), then \( w_1 = 1 \) and \( w_k \neq 1 \) (which we call Type 1), \( w_1 \neq 1 \) and \( w_k = 1 \) (Type 2), \( w_1 = 1 \) and \( w_k = 1 \) (Type 3), or \( w_1 \neq 1 \) and \( w_k \neq 1 \) (Type 4). Let \( w \) be an allowable word of Type 1. Then for any allowable words \( u, v \) in \( Y \) such that \( uuvv \) is allowable, we obtain \( |\pi^{-1}(uuvv)| \leq |\pi^{-1}(1)||\pi^{-1}(w)||\pi^{-1}(v)| \). Let \( i \in \mathbb{N} \). If we take \( u = i \) then \( |\pi^{-1}(i)| = i \) and \( |\pi^{-1}(i)| = 1 \). Therefore, (C2) implies that \(|\pi^{-1}(w)|/i \geq D \). Hence there exist \( N_1 \in \mathbb{N} \) such that if \( i \geq N_1 \) then for any pair \( i, v \), (C2) does not holds with \( iuv \) where \( w \) is of Type 1. By making similar arguments for \( w \) of Type 2, 3 and 4, there exists a pair \( i, j \in \mathbb{N} \) such that (C2) does hold by using a \( w \) from a finite set \( W \).
A fundamental result in thermodynamic formalism is the variational principle. It establishes a relation between the pressure (which is defined by means of the topological structure of the system) and the sum of the metric entropy and the integral with respect to an invariant measure (which is defined by means of the Borel structure of the system). The relation in the variational principle for a sequence of functions $\mathcal{F} = \{\log f_n\}_{n=1}^{\infty}$ is the following

$$P(\mathcal{F}) = \sup_{\mu \in M(X, \sigma)} \left\{ h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu : \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu > -\infty \right\},$$

where $M(X, \sigma)$ denotes the space of $\sigma$-invariant Borel probability measures. The goal of this section is to establish the variational principle for the types of sequences introduced in Section 2.2.

4.1. Variational principle for a countable Markov shift with the weak specification property without the finiteness condition (C3). The purpose of this section is to prove the variational principle for the Bowen sequences defined on countable Markov shifts satisfying (C1) and (C2). We do not assume the finiteness condition (C3). Hence in the proof of the approximation property (Proposition 4.1), this condition is not assumed. However, we see in Lemma 4.4 that if the pressure is finite, then the type of sequence we consider in this section is defined on a space with the finiteness condition.

The following is an important technical remark (see [MU2]). Since $X$ is an irreducible countable Markov shift, by rearranging the set $N$ of the symbols of $X$, there exists a transition matrix $A$ for $X$ and an increasing sequence $\{k_n\}_{n=1}^{\infty}$ such that the matrix $A|_{\{1, \ldots, k_n\} \times \{1, \ldots, k_n\}}$ is irreducible. Define $A_{k_n} := A|_{\{1, \ldots, k_n\} \times \{1, \ldots, k_n\}}$. We will assume the following property on the sequence of functions $\mathcal{F} = \{\log f_n\}_{n=1}^{\infty}$, where $f_n : Y \to \mathbb{R}^+$ are continuous functions.

(P1) There exists an increasing sequence $\{l_n\}_{n=1}^{\infty}$ and constants $D_1, p_1 > 0$ such that for each $l_n$ the matrix $A_{l_n}$ is irreducible and $\mathcal{F}|_{X_{A_{l_n}}}$ satisfies (C2) with constants $D_{l_n}$ and $p_{l_n} \in \mathbb{N}$ such that $D_{l_n} \geq D_1$, and $p_{l_n} \leq p_1$ for every $n \in \mathbb{N}$.

**Lemma 4.1.** If $\mathcal{F} = \{\log f_n\}_{n=1}^{\infty}$ is a Bowen sequence on an irreducible countable Markov shift $X$ satisfying (P1), then $\mathcal{F}$ satisfies (C2) and $X$ satisfies the weak specification property.

**Proof.** Let $u \in B_{l_n}(X)$ and $v \in B_{m}(X)$ for $n, m \in \mathbb{N}$. Then there exists $N \in \mathbb{N}$ such that $u, v$ are allowable words of $X_{A_{l_n}}$. Call $Y := X_{A_{l_n}}$. Then the Bowen property and (P1) imply that there exists $w \in B_k(Y)$, $0 \leq k \leq p_{l_n} \leq p_1$ such that

$$\sup\{f_{n+k}(x) : x \in [uvw]\} \geq \sup\{f_{n+k+y}(x) : x \in [uvw]\} \geq D_{l_n} \sup\{f_{n+y}(x) : x \in [v]\} \geq D_1  \sup\{f_{n}(x) : x \in [u]\} \sup\{f_{m}(x) : x \in [v]\}.$$
In particular, a Bowen sequence on a finitely irreducible Markov shift satisfying (C2) and (C3) is a sequence satisfying (P1) (see Corollary 4.1). In the following propositions and lemmas, we continue to use the notation from (P1) and Section 2.2. Let $a \in \mathbb{N}$ be a symbol of a countable alphabet. For a compact $\sigma$-invariant subset $Y$ of $X$, define $Z_n(\mathcal{F}|_Y, a) = \sum_{y: \sigma^n(y) = y, y_0 = a} f_n(y)$. We first show that with the assumption (P1) the topological pressure $P(\mathcal{F})$ and the Gurevich pressure $P_G(\mathcal{F})$ takes $\infty$ when $Z_1(\mathcal{F}) = \infty$.

**Lemma 4.2.** Let $(X, \sigma)$ be an irreducible countable Markov shift and $\mathcal{F} = \{f_n\}_{n=1}^\infty$ a sequence on $X$ with tempered variation satisfying (C1) and (P1). If $Z_1(\mathcal{F}) = \infty$, then $P(\mathcal{F}) = \infty$. Thus, equation (2.6) holds.

*Proof.* Let $f'_n(x) = e^C f_n(x)$ for all $x \in X$ and $\mathcal{F}' = \{f'_n\}_{n=1}^\infty$. Then the sequence $\mathcal{F}'$ is sub-additive and $P(\mathcal{F}) = P(\mathcal{F}')$. Note by Proposition 2.1 that we obtain $P_G(\mathcal{F}'|_{X_{l_n}}, a) = P(\mathcal{F}'|_{X_{l_n}})$ for each $l_n$. Since $g$ has tempered variation, if $Z_1(\mathcal{F}) = \infty$, then given $L > 0$, there exists $N \in \mathbb{N}$ such that $Z_1(\mathcal{F}|_{X_{l_n}}) > L$ and thus $Z_1(\mathcal{F}'|_{X_{l_n}}) > Le^C$. Let $Y := X_{l_N}$. Then (P1) implies that for each $n \in \mathbb{N}$ there exists $0 \leq i_n \leq p_1(n-1)$ such that

$$Z_{n+i_n}(\mathcal{F}'|_Y) \geq \left(\frac{D_1}{p_1+1}\right)^{n-1}(Z_1(\mathcal{F}'|_Y))^n,$$

where $D_1 = D_1/e^C$. Since we have $P(\mathcal{F}') \geq \limsup_{n \to \infty}(1/(n+i_n)) \log Z_{n+i_n}(\mathcal{F}'|_Y) = P(\mathcal{F}'|_Y)$, we obtain that $P(\mathcal{F}') \geq P(\mathcal{F}'|_Y) \geq d + (1/(p_1+1)) \log(Le^C)$ where $d = (1/(p_1+1)) \log(D_1/(p_1+1))$. Letting $L \to \infty$, we obtain $P(\mathcal{F}) = P(\mathcal{F}') = \infty$. To see that (2.6) holds, we apply Proposition 2.1. Since $P_G(\mathcal{F}|_Y, a) = P_G(\mathcal{F}'|_Y, a) = P(\mathcal{F}'|_Y)$ and $P_G(\mathcal{F}, a) \geq P_G(\mathcal{F}|_Y, a)$, the result follows by letting $L \to \infty$. \hfill \Box

The next result provides an approximation property by compact invariant sets for the pressure, without the finiteness condition (C3). We prove this by using the Gurevich pressure.

**Proposition 4.1.** Let $(X, \sigma)$ be an irreducible countable Markov shift. If $\mathcal{F} = \{f_n\}_{n=1}^\infty$ is a Bowen sequence on $X$ satisfying (C1) and (P1), then

$$P(\mathcal{F}) = \sup_{l_n, a \in \mathbb{N}} \left\{ P(\mathcal{F}|_{X_{l_n}}) \right\},$$

and $P(\mathcal{F}) \neq -\infty$.

*Proof.* We use similar arguments used in [Y1, Proposition 3.1]. First assume $Z_1(\mathcal{F}) < \infty$ and so $P(\mathcal{F}) < \infty$. Assume also that $-\infty < P(\mathcal{F})$ (we show that $P(\mathcal{F}) \neq -\infty$). Define $f'_n(x)$ and $\mathcal{F}'$ as in the proof of Lemma 4.2. Then the sequence $\mathcal{F}'$ is a sub-additive Bowen sequence and $P(\mathcal{F}) = P(\mathcal{F}')$. Let $a \in \mathbb{N}$ be a symbol of the countable alphabet of $X$. Then $P(\mathcal{F}') = \lim_{n \to \infty} B_n$, where $B_n = \sup_{k \geq n}(1/k) \log Z_k(\mathcal{F}', a)$ and $B_n < \infty$ for all $n \in \mathbb{N}$. Let $\epsilon > 0$ and fix $m \in \mathbb{N}$ such that

$$\frac{p_1}{m} < \epsilon \quad \text{and} \quad \frac{1}{m} \left| \log \frac{M(p_1+1)}{D_1} \right| < \epsilon.$$

Then there exists $q \in \mathbb{N}$, $q \geq m$ such that

$$B_m - \epsilon < \frac{1}{q} \log Z_q(\mathcal{F}', a) \leq B_m.$$

Thus,

$$P(\mathcal{F}') \leq B_m < \frac{1}{q} \log Z_q(\mathcal{F}', a) + \epsilon.$$
Since \( q \geq m \), (4.2) holds by replacing \( m \) by \( q \). Then \( Z_q(F', a) = \lim_{n \to \infty} Z_q(F'_{X_{A_{i_n}}}, a) \). Note that \( \{Z_q(F'_{X_{A_{i_n}}}, a)\}_{n=1}^\infty \) increases to \( Z_q(F', a) \) monotonically. Thus there exists \( n_1 \in \mathbb{N} \) such that

\[
\frac{1}{q} \log Z_q(F', a) < \frac{1}{q} \log Z_q(F'_{X_{A_{i_{n_1}}}}, a) + \epsilon.
\]

By (P1), \( F'_{X_{A_{i_{n_1}}}} \) satisfies (C2). Let \( Y = X_{A_{i_{n_1}}} \). Then \( Y \) has the weak specification property with a specification number \( p_Y \leq p_1 \).

**Lemma 4.3.** For \( n, m \in \mathbb{N} \), there exists \( 0 \leq i_{n,m} \leq p_Y \) such that

\[
\frac{(p_Y + 1)M}{D_1} Z_{n+m+n+m}(F'_{Y}, a) \geq Z_n(F'_{Y}, a)Z_m(F'_{Y}, a).
\]

**Proof.** Let \( n, m \in \mathbb{N} \) be fixed. Take \( x, y \in Y \) such that \( \sigma^n x = x \) and \( \sigma^m y = y \), where \( x_1 = y_1 = a \). Let \( x = (ax_2 \ldots x_{n-1})^\infty \) and \( y = (ay_2 \ldots y_{m-1})^\infty \). By (P1), there exist \( 0 \leq k \leq p_Y \) and an allowable word \( b_1 \ldots b_k \) in \( Y \) such that \( ax_2 \ldots x_{n-1}b_1 \ldots b_ay_2 \ldots y_{m-1} \) is allowable in \( Y \) satisfying (C2). Thus \( z = (ax_2 \ldots x_{n-1}b_1 \ldots b_ay_2 \ldots y_{m-1})^\infty \in Y \) and \( \sigma^{n+m+k}z = z \).

\[
M f_{m+n+m+k}'(z) \geq \sup \{ f_{m+n+m+k}'(x) : x \in [ax_2 \ldots x_{n-1}b_1 \ldots b_ay_2 \ldots y_{m-1}] \}
\]

\[
\geq D_1 \sup \{ f_m'(y) : y \in [ax_2 \ldots x_{n-1}] \} \sup \{ f_n'(y) : y \in [ay_2 \ldots y_{m-1}] \}
\]

\[
\geq D_1 f_m'(y) f_n'(y).
\]

Therefore

\[
M \sum_{k=0}^{p_Y} Z_{n+m+k}(F'_{Y}, a) \geq D_1 Z_n(F'_{Y}, a)Z_m(F'_{Y}, a).
\]

There exists \( 0 \leq i_{n,m} \leq p_Y \) such that

\[
\frac{(p_Y + 1)M}{D_1} Z_{n+m+i_{n,m}}(F'_{Y}, a) \geq Z_n(F'_{Y}, a)Z_m(F'_{Y}, a).
\]

\[\square\]

Setting \( m = n = q \) in Lemma 4.3, there exists \( 0 \leq i_1 \leq p_Y \) such that

\[
\left(\frac{(p_Y + 1)M}{D_1}\right)^{k-1} Z_{kq+i_1+\cdots+i_{k-1}}(F'_{Y}, a) \geq (Z_q(F'_{Y}, a))^k.
\]

Now let \( a_q = \log Z_q(F'_{Y}, a) \). Then

\[
a_q = \frac{\log(Z_q(F'_{Y}, a))^k}{kq} \leq \left(\frac{(p_Y + 1)M}{D_1}\right)^{k-1} \log Z_{kq+i_1+\cdots+i_{k-1}}(F'_{Y}, a).
\]

Since \( p_Y \leq p_1 \), letting \( k \to \infty \)

\[
a_q \leq \frac{1}{q} \limsup_{k \to \infty} \frac{1}{kq+i_1+\cdots+i_{k-1}} \log Z_{kq+i_1+\cdots+i_{k-1}}(F'_{Y}, a)
\]

\[
\leq \epsilon + (1 + \epsilon)P(F'_{Y}) \leq \epsilon(P(F') + 1) + P(F'_{Y}).
\]

Hence, using (4.3) and (4.4), we obtain

\[
P(F') \leq 2\epsilon + \epsilon(P(F') + 1) + P(F'_{Y}).
\]
Next assume that $Z_1(\mathcal{F}) = \infty$. Then the proof of Lemma 4.2 shows the result. To show $P(\mathcal{F}) \neq -\infty$, observe that (4.6) and (4.7) are valid for any $m, l_n \in \mathbb{N}$ if we replace $q$ and $Y$ by $m$ and $X_{l_n}$ respectively. Hence letting $k \to \infty$ in (4.7) implies that $P(\mathcal{F}) \neq -\infty$. □

**Proposition 4.2.** Let $(X, \sigma)$ be a subshift on a countable alphabet. If $\mathcal{F}$ a sequence on $X$ with tempered variation satisfying (C1) and (D2), then $P(\mathcal{F}) < \infty$ if and only if $Z_1(\mathcal{F}) < \infty$.

**Proof.** We claim that $P(\mathcal{F}) < \infty$ if and only if $Z_n(\mathcal{F}) < \infty$ for all $n \in \mathbb{N}$. This gives the result by noting that $Z_1(\mathcal{F}) < \infty$ if and only if $Z_n(\mathcal{F}) < \infty$ for all $n \in \mathbb{N}$. It is obvious that if $Z_n(\mathcal{F}) < \infty$ for all $n \in \mathbb{N}$, then $P(\mathcal{F}) < \infty$. If $P(\mathcal{F}) < \infty$, then there exists $N \in \mathbb{N}$ such that $Z_n(\mathcal{F}) < \infty$ for all $n \geq N$. Let $u_N \in B_N(X)$ and $v_1 \in B_1(X)$. Then by (D2) there exist $p \in \mathbb{N}$ and $w \in B_k(X), 0 \leq k \leq p$, such that $u_Nvw_1$ is allowable and

$$\sup\{f_{n+k+1}(x) : x \in [u_Nvw_1]\} \geq D_{N,1} \sup\{f_n(x) : x \in [u_N]\} \sup\{f_1(x) : x \in [v_1]\}.$$ 

Hence

$$\sum_{i=0}^{p} Z_{N+i+1}(\mathcal{F}) \geq D_{N,1} Z_N(\mathcal{F}) Z_1(\mathcal{F}).$$ 

Since $Z_N(\mathcal{F})$ is bounded below by a constant, we obtain that $Z_1(\mathcal{F}) < \infty$ and hence $Z_n(\mathcal{F}) < \infty$ for all $n \in \mathbb{N}$. □

**Remark 4.1.** See [MU2, Proposition 1.6] for a result related to Proposition 4.2.

**Lemma 4.4.** Let $\mathcal{F}$ be a Bowen sequence on a subshift $X$ on a countable alphabet satisfying (C1) and (C2). If $\mathcal{F}$ fails to have (C3), then $P(\mathcal{F}) = \infty$.

**Proof.** Assume $P(\mathcal{F}) < \infty$. By Claim 3.1, $\sum_{i=1}^{p} Z_i(\mathcal{F}) = \infty$. This is a contradiction to Proposition 4.2. □

**Remark 4.2.** Note that by Lemma 4.4 if $P(\mathcal{F}) \neq \infty$ then a Bowen sequence $\mathcal{F}$ satisfying (C1) and (C2) is defined on a finitely irreducible subshift. This motivates us to study a Gibbs measure for $\mathcal{F}$ (see [MU2, S3]).

The main goal of this section is to obtain the variational principle and the results of the rest of this section will also be applied in Section 4.2.

**Proposition 4.3.** Let $(X, \sigma)$ be a subshift on a countable alphabet and $\mathcal{F} = \{\log f_n\}_{n=1}^{\infty}$ be a sequence of continuous functions on $X$ with tempered variation satisfying (C1) and (D2). If $P(\mathcal{F}) < \infty$, then for any $\mu \in M(X, \sigma)$ such that $\lim_{n \to \infty} (1/n) \int \log f_n d\mu > -\infty$ we have

$$(4.8) \quad h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu \leq P(\mathcal{F}).$$

**Remark 4.3.** Assumptions of Proposition 4.3 imply that $\lim_{n \to \infty} (1/n) \int \log f_n d\mu$ exists, and possibly $-\infty$ (see the proof below). Note that (D2) implies that $P(\mathcal{F}) \neq -\infty$.

**Proof of Proposition 4.3.** We follow the proof of [MU2, Theorem 1.4]. We have to slightly modify the proof in order to take into account of the sub-additive sequence $\mathcal{F}' := \{\log(e^{C} f_n)\}_{n=1}^{\infty}$. Since $P(\mathcal{F}) < \infty$, Proposition 4.2 implies $Z_1(\mathcal{F}) < \infty$ and thus $sup f_1 < \infty$. Hence we obtain that $\int (\log e^{C} f_1)^+ d\mu < \infty$. Applying sub-additive ergodic theorem to $\mathcal{F}'$, we obtain that $\lim_{n \to \infty} (1/n) \int \log f_n d\mu$ exists for any $\mu \in M(X, \sigma)$. Note by Proposition 4.2 that $0 < Z_n(\mathcal{F}) < \infty$ for each $n \in \mathbb{N}$. Using the sub-additivity of $\mathcal{F}'$, it follows that for every $n, m \in \mathbb{N}$

$$\frac{1}{nm} \int \log f_{nm} d\mu \leq \frac{1}{n} \int \log f_n d\mu + \frac{C}{n}.$$
Thus
\[-\infty < \limsup_{n \to \infty} \frac{1}{nm} \int \log f_n \, d\mu \leq \frac{1}{n} \int \log f_n \, d\mu + \frac{C}{n},\]
and for each \( n \in \mathbb{N} \)
\[\sum_{w \in B_n(X)} \mu([w]) \log (\sup \{ f_n(x) : x \in [w] \}) \geq \int \log f_n \, d\mu > -\infty.\]

For \( n \geq 1 \), letting \( h(x) = -x \log x \), we have
\[- \sum_{w \in B_n(X)} \mu([w]) \log \mu([w]) + \int \log f_n \, d\mu \]
\[\leq \sum_{w \in B_n(X)} \mu([w]) (\log (\sup \{ f_n(x) : x \in [w] \}) - \log \mu([w])
\]
\[= Z_n(\mathcal{F}) \sum_{w \in B_n(X)} \frac{\mu([w])}{Z_n(\mathcal{F})} \frac{\mu([w])}{\sup \{ f_n(x) : x \in [w] \}} h\left( \frac{\mu([w])}{\sup \{ f_n(x) : x \in [w] \}} \right)
\]
\[\leq Z_n(\mathcal{F}) h \left( \sum_{w \in B_n(X)} \frac{\mu([w])}{Z_n(\mathcal{F})} \right) \leq Z_n(\mathcal{F}) h \left( Z_n(\mathcal{F})^{-1} \right) = \log Z_n(\mathcal{F}),\]
where in the third inequality we use the concavity of \( h \). Therefore, for every \( n \geq 1 \) we have that
\[- \sum_{w \in B_n(X)} \mu([w]) \log \mu([w]) < \infty.\]
In particular, if we let \( \alpha = \{[u] : u \in B_1(X)\} \), then \( \alpha \) is a generator for \( \sigma \). Hence
\[h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu \leq \lim_{n \to \infty} \left( -\frac{1}{n} \sum_{w \in B_n(X)} \mu([w]) \log \mu([w]) + \frac{1}{n} \int \log (e^C f_n) \, d\mu \right) \leq P(\mathcal{F}).\]

\[\square\]

**Lemma 4.5.** Let \((X, \sigma)\) and \(\mathcal{F} = \{\log f_n\}_{n=1}^\infty\) be defined as in Proposition 4.3. If \(P(\mathcal{F}) = \infty\), then for any \(\mu \in M(X, \sigma)\) such that \(\limsup_{n \to \infty} (1/n) \int \log f_n \, d\mu > -\infty\),
\[(4.9) \quad h_\mu(\sigma) + \limsup_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu \leq P(\mathcal{F}).\]

If \(\sup f_1 < \infty\), then \(\limsup\) can be replaced by \(\lim\).

**Proof.** The result is obvious. \(\square\)

To show the variational principle, we need the following variational principle for sequences on subshifts on finite alphabets (see [CFH]).

**Theorem 4.1.** [CFH] Let \((X, \sigma)\) be a subshift on a finite alphabet. If \(\mathcal{F} = \{\log f_n\}_{n=1}^\infty\) is a sequence on \(X\) with tempered variation satisfying (C1), then
\[P(\mathcal{F}) = \sup_{\mu \in M(X, \sigma)} \left\{ h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu \right\},\]
where \(P(\mathcal{F})\) is defined in Definition 2.8. Then \(P(\mathcal{F}) = -\infty\) if and only if \(\lim_{n \to \infty} (1/n) \int \log f_n \, d\mu = -\infty\) for all \(\mu \in M(X, \sigma)\).

In Theorem 4.1 an equilibrium measure for \(\mathcal{F}\) (see Definition 5.1) always exists.
Theorem 4.2. Let \((X, \sigma)\) be an irreducible countable Markov shift and \(\mathcal{F} = \{\log f_n\}_{n=1}^{\infty}\) be a Bowen sequence on \(X\) satisfying (C1) and (P1). If \(P(\mathcal{F}) < \infty\), then

\[
(4.10) \quad P_G(\mathcal{F}) = P(\mathcal{F}) = \sup_{\mu \in M(X, \sigma)} \left\{ h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu : \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu > -\infty \right\}.
\]

In particular, if \(\mathcal{F}\) satisfies (C2) with the strong specification, then \(\limsup\) in (2.5) of the definition \(P_G(\mathcal{F})\) can be replaced by \(\lim\). If \(P(\mathcal{F}) = \infty\), then

\[
(4.11) \quad P_G(\mathcal{F}) = P(\mathcal{F}) = \sup_{\mu \in M(X, \sigma)} \left\{ h_\mu(\sigma) + \limsup_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu : \limsup_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu > -\infty \right\}.
\]

In particular, if \(\sup f_1 < \infty\), equation (4.10) holds for the case when \(P(\mathcal{F}) = \infty\).

**Proof.** First assume that \(P(\mathcal{F}) < \infty\). Let \(\epsilon > 0\). Applying Proposition 4.1, there exists a finite state Markov shift \(Y\) such that \(P(\mathcal{F}) - P(\mathcal{F}|_Y) < \epsilon\). Let \(m\) be an equilibrium measure for \(\mathcal{F}|_Y\). Since \(m \in M(X, \sigma)\) and \(\lim_{n \to \infty} \frac{1}{n} \int \log f_n \, dm > -\infty\), we obtain

\[
\begin{align*}
& h_m(\sigma_Y) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, dm \\
& \leq \sup_{\mu \in M(X, \sigma)} \left\{ h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu : \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu > -\infty \right\}.
\end{align*}
\]

Thus

\[
P(\mathcal{F}) - \epsilon \leq P(\mathcal{F}|_Y) \leq \sup_{\mu \in M(X, \sigma)} \left\{ h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu : \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu > -\infty \right\} \leq P(\mathcal{F}).
\]

Hence we obtain the result. Equation (4.11) holds for \(P(\mathcal{F}) = \infty\) by similar arguments using Lemma 4.5. The last statement is obvious. \(\square\)

Corollary 4.1. Let \((X, \sigma)\) be a countable Markov shift. If \(\mathcal{F}\) a Bowen sequence on \(X\) satisfying (C1), (C2) and (C3), then Propositions 4.1 and 4.3, Lemma 4.5 and Theorem 4.2 hold.

**Proof.** It suffices to show that (P1) is satisfied. Let \(W\) be a finite set from (C3). Since \(X\) is an irreducible countable Markov shift, let \(A_n\) be defined as in the beginning of this section. Take \(l_q\) large enough so that \(\{1, \ldots, l_q\}\) contains all the symbols that appear in \(W - \{\varepsilon\}\). Then, for \(n \geq q\), \(\mathcal{F}|_{X_{A_n}}\) satisfies (C2) replacing \(D\) by \(D/M\). \(\square\)

Remark 4.4. \((X, \sigma)\) in Corollary 4.1 is finitely irreducible by (C2) and (C3). The case when \(X\) is the full shift on a countable alphabet has been studied by [KR].

Example 4.1. In Example 3.8, the sequence \(\Phi\) defined on the countable Markov shift \(Y\) satisfies (C1). Here we show that (P1) holds. Let \(X_n\) be the subshift of \(X\) on the symbols \(\{F_1, \ldots, F_n\}\). Let \(Y_n = \pi(X_n)\). Then \(Y_n\) is an irreducible finite Markov shift on \(\{1, \ldots, n\}\). For \(n \geq 3\), each \(\Phi|_{Y_n}\) satisfies (C2) with \(p = 3\) and \(D = 1\). Hence (P1) is satisfied. Thus Proposition 4.1 and Theorem 4.2 hold. Since (C3) is not satisfied, by Lemma 4.4, \(P(\Phi) = P_G(\Phi) = \infty\) and equation (4.11) holds.

Example 4.2. In Example 3.4, the sequence \(\Psi = \{\log \psi_n\}_{n=1}^{\infty}\) defined on the countable Markov shift \(Y\) satisfies (C1), (C2) and (C3). Hence Proposition 4.1 and Theorem 4.2 hold. Since \(\Psi\) satisfies (C2) with the strong specification, \(P(\Psi) = P_G(\Psi) = \lim_{n \to \infty} \frac{1}{n} \log Z_n(\Psi, a)\) for all \(a \in \mathbb{N}\). Since \(k \geq 3\), we obtain \(Z_k(\Psi) = \sum_{i \in \mathbb{N}} (1/k^{-1}(i/k^{-1}) \leq \sum_{i \in \mathbb{N}} (1/k^{-1} < \infty\). Therefore, \(P(\Psi) < \infty\) and equation (4.10) holds.
4.2. Variational principle for finitely irreducible countable sofic shifts. In this section, we prove the variational principle for sequences $F$ with tempered variation (see Definition 2.7) on finitely irreducible countable sofic shifts (see Definition 2.11). Therefore the space $X$ is not a Markov shift and it has the finiteness property. The regularity condition on $F$ is weaker than what was assumed in Section 4.1. Our approach here is based on the proof of [MU2, Theorem 1.2].

Let $(X, \sigma)$ be an irreducible countable sofic shift. Then by Definition 2.11 there exist an irreducible countable Markov shift $(\bar{X}, \sigma_{\bar{X}})$ and a one-block factor map $\pi: \bar{X} \to X$ such that $|\pi^{-1}(i)| < \infty$ for each $i \in \mathbb{N}$. Rearranging the set $\mathbb{N}$, there is a transition matrix $A$ for $\bar{X}$ and an increasing sequence $\{l_n\}_{n=1}^{\infty}$ such that the matrix $A_{l_n} = A|_{\{1, \ldots, l_n\} \times \{1, \ldots, l_n\}}$ is irreducible. For each $n \in \mathbb{N}$, let $S_n = \{\pi(i) : 1 \leq i \leq l_n\}$. Then $(\bar{X}_{l_n}, \sigma_{\bar{X}_{l_n}})$ is a sofic shift on the set $S_n$ of finitely many symbols. Clearly, $\pi(\bar{X}_{l_n}) \subseteq \pi(\bar{X}_{l_{n+1}}) \subset X$ and $\mathbb{N} = \cup_{n \in \mathbb{N}} S_{l_n}$. We note that we can extract a subsequence $\{l_{n_j}\}_{j=1}^{\infty}$ such that $\pi(\bar{X}_{l_{n_j}}) \subset \pi(\bar{X}_{l_{n_{j+1}}}) \subset X$ for all $n_j, j \in \mathbb{N}$.

We continue to use the notation above throughout this section. The following lemma is important and will be also applied in Section 5.

**Lemma 4.6.** Let $(X, \sigma)$ be an irreducible countable sofic shift and $F = \{\log f_n\}_{n=1}^{\infty}$ a sequence on $X$ with tempered variation satisfying (D2) and (D3). Let $p$ be defined as in (D2) and $W$ be defined as in (D3). Then there exists $q \in \mathbb{N}$ such that for each $k \geq q$ there exists an irreducible subshift $(X_{l_k}, \sigma_{X_{l_k}})$ on the set $S_{l_k}$ of finitely many symbols such that $\pi(X_{l_{k+1}}) \subset X_{l_k} \subset X$. Moreover, for any $n, m \in \mathbb{N}, k \geq q, u \in B_n(X_{l_k}), v \in B_m(X_{l_k})$, there exists $w \in W$ such that $uvw$ is an allowable word of $X_{l_k}$ and

$$\sup\{f_{n+m+|w|} | x \in [uvw] \} \leq \frac{D_{n, m}}{M_{n+m+p}} \sup\{f_n | x \in [u]\} \sup\{f_m | x \in [v]\},$$

where $M_n$ is defined as in Definition 2.7.

**Remark 4.5.** If $F$ is a Bowen sequence, (4.12) implies that (C2) holds for $F|_{X_{l_k}}, k \geq q$, replacing $D$ in (C2) by $D/M$.

**Proof.** Since $(X, \sigma)$ is an irreducible countable sofic shift, there exist an irreducible countable Markov shift $(\bar{X}, \sigma_{\bar{X}})$ and a one-block factor map $\pi: \bar{X} \to X$ such that $|\pi^{-1}(i)| < \infty$ for each $i \in \mathbb{N}$. Since $W$ is a finite set, only finitely many symbols appear in $W$. We first consider the case when $W$ contains a nonempty allowable word. Call $S_W$ the set of symbols that appear in $W - \{\}$.

Let $\pi^{-1}(S_W)$ be the set of preimages of the symbols of $S_W$ in $X$. Then $\pi^{-1}(S_W)$ is a finite set because $|\pi^{-1}(i)| < \infty$ for each $i \in \mathbb{N}$.

Now consider a transition matrix $A$ for $\bar{X}$ and an increasing sequence $\{l_k\}_{k=1}^{\infty}$ such that the matrix $A_{l_k} = A|_{\{1, \ldots, l_k\} \times \{1, \ldots, l_k\}}$ is irreducible for each $l_k$. Then there exists $q \in \mathbb{N}$ such that $\pi^{-1}(S_W) \subset \{1, \ldots, l_k\}$ for all $k \geq q$. Thus, for $k \geq q$ the subshift $(\pi(X_{l_k}), \sigma_{\pi(X_{l_k})})$ is a sofic shift on the set $S_{l_k}$ of finitely many symbols that contains $S_W$. For a fixed $k \geq q$, consider the set $\pi^{-1}(S_{l_k})$ of the preimages of the set $S_{l_k}$ and call it $P$. Then $P$ contains $\{1, \ldots, l_k\}$ and it is a finite set. Let $Y_P$ be the finite state Markov shift on the symbols of $P$ and define $Y = \pi(Y_P)$. Then $Y$ is a subshift on the set of $S_{l_k}$ of finitely many symbols which contains $S_W$. Observe that $\pi(X_{l_k}) \subseteq Y \subset X$.

We observe that $Y$ is irreducible. Fix $n, m \in \mathbb{N}$. Let $u = u_1 \ldots u_n \in B_n(Y)$ and $v = v_1 \ldots v_m \in B_m(Y)$. Since these are allowable words of $X$, there exists $w = w_1 \ldots w_l \in W$, $0 \leq l \leq p$, such that $uvw$ is allowable in $X$ and (D2) holds. Since $uvw$ is allowable in $X$, there exists $\bar{u}_1 \ldots \bar{u}_n \bar{u}_1 \ldots \bar{v}_1 \ldots \bar{v}_m \in B_n+m+l(\bar{X})$ such that $\pi(\bar{u}_1 \ldots \bar{u}_n \bar{u}_1 \ldots \bar{v}_1 \ldots \bar{v}_m) = uvw$. Since all the symbols that appear in the preimages of $u, v, w$ are in the set $P$, we obtain that $\bar{u}_1 \ldots \bar{u}_n \bar{u}_1 \ldots \bar{v}_1 \ldots \bar{v}_m \in B_{n+m+l}(\bar{Y}_P)$. Therefore, $uvw$ is allowable in $Y$ and $Y$ is irreducible.
Using the property of tempered variation,
\[
\sup\{f_{n+m+|w|} : y \in [uvw]\} \geq \frac{1}{M_{n+m+p}} \sup\{f_{n+m+|w|}(x) : x \in [uvw]\}
\]
\[
\geq \frac{D_{n,m}}{M_{n+m+p}} \sup\{f_n(x) : x \in [u]\} \sup\{f_m(x) : x \in [v]\}
\]
\[
\geq \frac{D_{n,m}}{M_{n+m+p}} \sup\{f_n(y) : y \in [u]\} \sup\{f_m(y) : y \in [v]\}.
\]

For each \(k \geq q\), we can construct a such \(Y\). Setting \(Y = X_{t_k}\), we obtain the results. If \(W = \{\varepsilon\}\), we make a similar argument.

\[\square\]

Under the setting of Lemma 4.6, we define the topological pressure \(P(F)\) as in Definition 2.8. By Proposition 4.2 we have \(Z_1(F) < \infty\) if and only if \(P(F) < \infty\). We note that if \(Z_1(F) = \infty\), then \(P(F) = \infty\) and the proof is given in that of Theorem 4.3.

**Theorem 4.3.** Let \((X, \sigma)\) be an irreducible countable sofic shift. If \(F = \{\log f_n\}_{n=1}^{\infty}\) is a sequence on \(X\) with tempered variation satisfying (C1), (D2) and (D3), then

\[P(F) = \sup_{n \geq q} \{P(F|_{X_{t_n}})\}\]

\[= \sup_{Y \subset X} \{P(F|_{Y})\} : Y \subset X \text{ is an irreducible sofic shift on a finite alphabet}\},\]

where \(X_{t_k}, q\) are defined as in Lemma 4.6, and \(P(F) \neq -\infty\). The variational principle holds. If \(P(F) < \infty\), then

\[P(F) = \sup_{\mu \in M(X, \sigma)} \left\{h_{\mu}(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu : \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu > -\infty\right\}.
\]

If \(P(F) = \infty\), then

\[P(F) = \sup_{\mu \in M(X, \sigma)} \left\{h_{\mu}(\sigma) + \limsup_{n \to \infty} \frac{1}{n} \int \log f_n d\mu : \limsup_{n \to \infty} \frac{1}{n} \int \log f_n d\mu > -\infty\right\}.
\]

**Remark 4.6.** Condition (D3) implies that \((X, \sigma)\) is a finitely irreducible countable sofic shift. If \(sup f_1 < \infty\), then (4.15) also holds for the case when \(P(F) = \infty\).

**Proof.** We first consider the case when \(Z_1(F) < \infty\). Then \(P(F) < \infty\) by Proposition 4.2. Note that there exist an irreducible countable Markov shift \((\bar{X}, \bar{\sigma}\bar{X})\) and a one-block factor map \(\pi : \bar{X} \to X\) such that \(|\pi^{-1}(i)| < \infty\) for each \(i \in \mathbb{N}\). We show first (4.13) using a modification of the proof of [MU2, Theorem 1.2]. As in the proof of Proposition 4.1 let \(f'(x) = e^{C}f_n(x)\) and \(F' = \{\log f'_n\}_{n=1}^{\infty}\). Then \(F'\) is sub-additive and \(P(F) = P(F')\). Let \(M\) be defined for \(F\) as in Definition 2.7.

Let \(\epsilon > 0\). Fix \(m \in \mathbb{N}\) such that \((1/m) \log M_m < \epsilon\), \((1/(m+p)) \log(D_{m,m}/e^{C}) < \epsilon\) and \(1 - \epsilon < (m/(m+p))\). Note that \(Z_m(F') < \infty\).

We apply Lemma 4.6 and consider \(X_{t_k}\) where \(k \geq q\). Then for each \(n \in \mathbb{N}\), we have

\[Z_n(F'|_{X_{t_k}}) = \sum_{w \in B_m(X_{t_k})} \sup\{f'_n|_{X_{t_k}}(x) : x \in [w]\}.
\]

Since \(w \in B_m(X_{t_k})\) implies that \(w \in B_m(X)\), let \(S_{t_k}(F') := \sum_{w \in B_m(X_{t_k})} \sup\{f'_m(x) : x \in [w]\}\). Noting that for each \(x_1\ldots x_m \in B_m(X)\), there exists \(i \in \mathbb{N}\) such that \(x_1\ldots x_m \in B_m(X_{t_i})\),

\[Z_m(F') = \lim_{i \to \infty} S_{t_i}(F'),\]
where \( \{S_t(F')\}_{t=1}^{\infty} \) is monotone increasing. Hence, for every \( \epsilon > 0 \), there exists \( k_1 > q \) such that

\[
(4.19) \quad \frac{1}{m} \log Z_m(F') - \frac{1}{m} \log S_{k_1}(F') < \epsilon.
\]

Since \( F \) has tempered variation, we have that \( M_mZ_m(F'\mid X_{k_1}) \geq S_{k_1}(F') \). Since \( F' \) is sub-additive, we obtain

\[
(4.20) \quad \frac{1}{m} \log Z_m(F'\mid X_{k_1}) \geq \frac{1}{m} \log Z_m(F') - \epsilon - \frac{m}{M_m} \geq P(F') - 2\epsilon.
\]

Now, for \( 0 \leq i \leq n, n \in \mathbb{N} \), let \( u_i \in B_m(X_{k_1}) \). Since \( F \) satisfies (D2) and (D3), letting \( W \) be a finite set from (D3), there exist \( w_1, \ldots, w_{n-1} \) in \( W \) such that \( u_1u_2 \ldots u_{n-1}u_n \) is an allowable word of length \( nm + |w_1| + \cdots + |w_{n-1}| \) of \( X \), such that

\[
(4.21) \quad \sup\{f'_{nm+|w_1|+\cdots+|w_{n-1}|}(x) : x \in [u_1u_2 \ldots u_{n-1}u_n]\} \geq \left(\frac{D_{m,m}}{e^C}\right)^{n-1} \prod_{i=1}^{n} \sup\{f'_m(x) : x \in [u_i]\}.
\]

By the construction of \( X_{k_1} \), \( k \geq q \), in the proof of Lemma 4.6, we note that \( u_1u_2 \ldots u_{n-1}u_n \) is an allowable word of \( X_{k_1} \). Therefore,

\[
M_{nm+p(n-1)} \sup\{f'_{nm+|w_1|+\cdots+|w_{n-1}|}(x) : x \in [u_1u_2 \ldots u_{n-1}u_n]\} \geq \left(\frac{D_{m,m}}{e^C}\right)^{n-1} \prod_{i=1}^{n} \sup\{f'_m(x) : x \in [u_i]\}.
\]

Summing over all allowable words \( u_i \in B_m(X_{k_1}) \), \( 0 \leq i \leq n \), we obtain

\[
\sum_{0 \leq i \leq p(n-1)} Z_{nm+|w_1|+\cdots+|w_{n-1}|}(F'\mid X_{k_1}) \geq \left(\frac{D_{m,m}}{e^C}\right)^{n-1} \cdot \frac{1}{M_{nm+p(n-1)}} \cdot \frac{1}{p(n-1)+1} \cdot \left(Z_m(F'\mid X_{k_1})\right)^{n}.
\]

Hence, there exists \( 0 \leq i, m \leq p(n-1) \) such that

\[
Z_{nm+i,m}(F'\mid X_{k_1}) \geq \left(\frac{D_{m,m}}{e^C}\right)^{n-1} \cdot \frac{1}{M_{nm+p(n-1)}} \cdot \frac{1}{p(n-1)+1} \cdot \left(Z_m(F'\mid X_{k_1})\right)^{n}.
\]

Thus

\[
\frac{1}{nm+i,m} \log(Z_{nm+i,m}(F'\mid X_{k_1})) \geq \frac{1}{nm+p(n-1)} \log\left(\frac{1}{M_{nm+p(n-1)}} \cdot \frac{1}{p(n-1)+1} + \frac{n}{nm+p(n-1)} \log Z_m(F'\mid X_{k_1})\right).
\]

Letting \( n \to \infty \) and using (4.20) we have,

\[
(4.23) \quad \limsup_{n \to \infty} \frac{1}{nm+i,m} \log(Z_{nm+i,m}(F'\mid X_{k_1})) \geq \frac{1}{m+p} \log \frac{D_{m,m}}{e^C} + \frac{m}{m+p} \cdot \frac{1}{m} \log Z_m(F'\mid X_{k_1}) \geq -2\epsilon - \epsilon P(F') + 2\epsilon^2 + P(F').
\]

Therefore, we obtain (4.13).
Next assume $Z_1(\mathcal{F}) = \infty$. We first show that $P(\mathcal{F}) = \infty$. Given $L > 0$, there exists $X_{l_*}, s \geq q$ such that $Z_1(\mathcal{F}|X_{l_*}) > L$. Then $Z_1(\mathcal{F}'|X_{l_*}) > Le^C$. Let $Y := X_{l_*}$. Then for each $n \in \mathbb{N}$ there exists $0 \leq i_{n,1} \leq p(n-1)$ such that

$$
\frac{1}{n + i_{n,1}} \log \left( Z_{n+i_{n,1}}(\mathcal{F}'|Y) \right) 
\geq \frac{1}{n + p(n-1)} \log \left( \frac{D_{1,1}}{e^C} \right)^{n-1} \cdot \frac{1}{M_{n+p(n-1)}} \cdot \frac{1}{p(n-1)+1} + \frac{n}{n + p(n-1)} \log Z_1(\mathcal{F}'|Y).
$$

(4.24)

A similar argument as in the proof of Lemma 4.2 implies $P(\mathcal{F}) = \infty$. The approximation property (4.13) is obvious from (4.24).

Since Propositions 4.2, 4.3 and Lemma 4.5 hold, the same proof (using the approximation property (4.13)) as in the proof of Theorem 4.2 yields the variational principle, equations (4.15) and (4.16). It is easy to see that (4.14) holds by Lemma 4.6 and its proof.

In the following, we study a condition for which $P(\mathcal{F})=P_G(\mathcal{F})$, when $\mathcal{G}$ is defined on a countable sofic shift.

**Proposition 4.4.** Let $(X, \sigma)$ be a finitely irreducible countable sofic shift. If $\mathcal{G}$ is an almost-additive sequence on $X$ with tempered variation, then $P(\mathcal{G}) = P_G(\mathcal{G})$. In particular, if $X$ is a factor of a finitely primitive countable Markov shift and $P(\mathcal{G}) < \infty$, then $\limsup$ in (2.5) can be replaced by $\lim$.

**Proof.** First assume $Z_1(\mathcal{G}) < \infty$. Thus $P(\mathcal{G}) < \infty$. Since $X$ is a finitely irreducible countable sofic shift, let $\bar{x}$ and $\pi: \bar{x} \to X$ be as in the proof of Lemma 4.6. Let $p \in \mathbb{N}$ and a finite set $W_1$ be defined for $X$ as in Definition 2.3. We consider the case when $W_1 \neq \{\varepsilon\}$. Let $x_1 \ldots x_n \in B_n(X)$ and $a \in \mathbb{N}$ be a symbol in $X$. Then there exist allowable words $w_1, w_2$ in $W_1$ of length $0 \leq k_1, k_2 \leq p$ respectively such that $aw_1x_1 \ldots x_n w_2 a \in B_{n+k_1+k_2}(X)$. Therefore, there exist $\bar{x}, \bar{x_1}, \ldots, \bar{x_n} \in \pi^{-1}(x_1 \ldots x_n)$, $a_1, a_2 \in \pi^{-1}(a)$, $\bar{w_1} \in \pi^{-1}(w_1)$ and $\bar{w_2} \in \pi^{-1}(w_2)$ such that $a_1 \bar{w_1} \bar{x_1} \ldots \bar{x_n} \bar{w_2} \bar{a_2} \in B_{n+k_1+k_2+2}(X)$ and $\pi(a_1 \bar{w_1} \bar{x_1} \ldots \bar{x_n} \bar{w_2} \bar{a_2}) = aw_1 \bar{x_1} \ldots \bar{x_n} \bar{w_1} \bar{a_1} a_2$. Since $|\pi^{-1}(a)| < \infty$, we have $\pi^{-1}(a) = \{a_1, \ldots, a_t\}$ for some $t \in \mathbb{N}$. For each pair $a_1, a_2, 1 \leq i, j \leq t$, define $k_{i,j} = \min\{|w|: a_i w_j \in B_{2+|w|}(\bar{x}), |w| \geq 1\}$. Then for each $i, j$, there exist a word at which the minimum is attained and we call it $\bar{w}_{i,j} \in B_{k_{i,j}}(\bar{x})$. Let $\pi(\bar{w}_{i,j}) = w_{i,j}$.

Now let $\bar{x} = (a_1 \bar{w_1} \bar{x_1} \ldots \bar{x_n} \bar{w_2} \bar{a_2} \bar{w_2} \bar{a_2}) \in \bar{x}$ and $x = \pi(\bar{x})$. Then $x$ has a period $(n+2+k_1+k_2+k_3)$. We first consider the case when $k_1, k_2$ are both nonzero. Since $\mathcal{G}$ is almost-additive and has tempered variation, letting $N_a = \sup\{f_i(x): x \in [a]\}$, we obtain

$$
g_{n+k_1+k_2+k_3+1}(x) \geq e^{-5C} \frac{M_n(M_p)^2(M_1)^2M_K}{\sup\{g_n(x) : x \in [x_1 \ldots x_n]\}(N_a)^2 \sup\{g_{k_1}(x) : x \in [w_1]\}} \sup\{g_{k_2}(x) : x \in [w_2]\} \sup\{g_{k_3}(x) : x \in [w_2]\}
$$

(4.25)

Since $g$ has tempered variation, for each $1 \leq i, j \leq t$, there exists constant $C_{w_{i,j}} > 0$ such that $\sup\{g_{k_{i,j}}(x) : x \in [w_{i,j}]\} > C_{w_{i,j}}$. Since we have finitely many $i, j$, let $B = \min_i, j C_{w_{i,j}}$, and $K = \max_i, j k_{i,j}$.

Now we consider the case when at least one of $k_1, k_2$ is 0. Observe that if $k_1$ is 0, then we replace $\sup\{g_{k_1}(x) : x \in [w_1]\}$ in (4.25) by 1. This applies also to $k_2$. Clearly there exists $b > 0$ such that $\min_{w \in W_1, |w| \geq 1} \sup\{g_i(x) : x \in [w]\} > b$. Let $\bar{D}' = \min\{1, \bar{D}\}$. Then, (4.25) implies that

$$
\sum_{0 \leq i \leq 2p+K} Z_{n+i+2}(\mathcal{G}, a) \geq e^{-5C} \frac{M_n(M_p)^2(M_1)^2M_K}{\sup\{g_n(x) : x \in [x_1 \ldots x_n]\}(N_a)^2 b \bar{D}'^2}.
$$

(4.26)
Thus similar arguments as in the proof of Proposition 2.1 yield
\[
\limsup_{n \to \infty} \frac{1}{n} \log Z_n(\mathcal{G}, a) \geq \limsup_{n \to \infty} \frac{1}{n} \log Z_n(\mathcal{G}).
\]
Since \(a\) is arbitrary, we obtain the result.

Next assume that \(Z_1(\mathcal{G}) = \infty\). Then \(P(\mathcal{G}) = \infty\). Let \(\mathcal{G}' = C + \mathcal{G}\). Given \(L > 0\), there exists \(X_L, s \geq q\) such that \(Z_1(\mathcal{G}|_{X_L}) > L\). Let \(Y := X_L\). Then (4.24) holds if we replace \(\mathcal{F}'\) by \(\mathcal{G}'\). Since \(P(\mathcal{G}'|_Y) = P_{\mathcal{G}}(\mathcal{G}'|_Y)\), similar arguments as in the proof of Lemma 4.2 imply \(P_{\mathcal{G}}(\mathcal{G}) = \infty\). To show the second statement, we use the similar arguments as in the proof of Proposition 2.1. If \(\bar{X}\) is a finitely primitive countable Markov shift, let \(p\) be a strong specification number for \(\bar{X}\) and set \(k_1 = k_2 = K = p\).

Note that Theorem 4.3 generalizes the thermodynamic formalism on non-compact shifts, including now irreducible countable sofic shifts. Indeed,

**Corollary 4.2.** Let \((X, \sigma)\) be a finitely irreducible countable sofic shift. If \(\mathcal{F}\) is an almost-additive sequence on \(X\) with tempered variation, then Theorem 4.3 holds for \(\mathcal{F}\) and \(P(\mathcal{F}) = P_{\mathcal{G}}(\mathcal{F})\). In particular, Theorem 4.3 holds for a continuous function \(f\) on \(X\) with tempered variation by setting \(f_n(x) = e^{S_n f(x)}\) for all \(x \in X\).

**Proof.** By Lemma 3.1, \(\mathcal{F}\) satisfies (C1), (D2) and (D3). For the last statement, we also apply Example 3.1. \(\square\)

**Remark 4.7.** The variational principle is proved in [MU2, Theorem 1.5] for acceptable functions (uniformly continuous functions with an additional property) on finitely irreducible countable Markov shifts. Applying [FFY, Proposition 6.2], it is easy to see that acceptable functions belong to the class of continuous functions with tempered variation. In [FFY, Theorem 2.4], the variational principle is studied for continuous functions with tempered variation on irreducible countable Markov shifts, without the finiteness condition on each \(M_n\). We also note that Corollary 4.2 generalizes the variational principle [Y1, Theorem 3.1] to that for almost-additive sequences with tempered variation on finitely irreducible countable sofic shifts.

Next we consider examples of Theorem 4.3.

**Example 4.3.** Let \(\mathcal{G}\) be defined as in Theorem 6.2. Then \(\mathcal{G}\) is a Bowen sequence defined on a finitely irreducible countable sofic shift satisfying (C1), (D2) and (D3). Note that \(\mathcal{G}\) does not satisfy (C2). Theorem 4.3 is applied in Theorem 6.2. See Section 6 for more details.

**Example 4.4.** In Example 3.5, the sequence \(\Psi = \{\log \psi_n\}_{n=1}^{\infty}\) defined on an irreducible countable sofic shift \(Y\) satisfies (C1), (C2) and (C3). Hence Theorem 4.3 holds. Since \(Z_1(\Psi) \leq C_2 \sum_{i \in \mathbb{N}} (1/i^2) < \infty\), we obtain \(P(\Psi) < \infty\) and equation (4.15) holds.

**Example 4.5.** In Example 3.6, define for \(i \in \mathbb{N}\)
\[
L_i := \frac{|\pi^{-1}(i+1)|}{|\pi^{-1}(i)|K}.
\]
Choose \(K > 0\) and define a factor map \(\pi\) such that \(\lim_{i \to \infty} L_i\) exists and \(L := \lim_{i \to \infty} L_i < 1\). Then the sequence \(\Psi = \{\log \psi_n\}_{n=1}^{\infty}\) defined on a finitely irreducible countable sofic shift \(Y\) satisfies (C1), (C2) and (C3). Hence Theorem 4.3 holds. Since \(Z_1(\Psi) < \infty\) by using the ratio test, we obtain \(P(\Psi) < \infty\) and equation (4.15) holds. If there exists \(l \in \mathbb{N}\) such that \(\pi^{-1}(i) \leq l\) for all \(i \in \mathbb{N}\) and \(K > 1\), then the same results hold. If we define a constant \(K > 0\) and a factor map \(\pi\) so that \(L > 1\), then \(P(\Psi) = \infty\) and equation (4.16) holds.
5. Invariant Gibbs measures and uniqueness of Gibbs equilibrium measures

The variational principle provides a criteria to choose relevant invariant measures for the (very large) set \( M(X, \sigma) \) of invariant Borel probability measures. Indeed, measures that maximize the supremum have interesting ergodic properties. Major difficulties to prove the existence of these measures are the fact that the space \( M(X, \sigma) \) is not compact (when endowed with the weak* topology) and that the entropy map \( \mu \mapsto h_\mu(\sigma) \) is not necessarily upper-semi continuous. Despite this we prove that under certain assumptions on the system and the class of sequence of functions such measures do exist. Moreover, they satisfy the so called Gibbs property which relates the measure of a cylinder of length \( n \) with the function \( f_n \). This property turns out to be very useful in a wide range of applications, for example in dimension theory of dynamical systems. The goal of this section is to prove under some conditions the existence and uniqueness of ergodic Gibbs measures for the Bowen sequences on finitely irreducible countable sofic shifts and the uniqueness of equilibrium states. The results are presented in Section 5.1 and the proofs of some technical lemmas are to be found in Section 5.2.

5.1. Invariant Gibbs measures and uniqueness of Gibbs equilibrium measures. Throughout this section, we assume that \( \mathcal{F} = \{ \log f_n \}_{n=1}^\infty \) is a sequence defined on a finitely irreducible countable sofic shift \((X, \sigma)\) satisfying (C1), (C2), (C3) and (C4).

**Definition 5.1.** Let \((X, \sigma)\) be a subshift on a countable alphabet and \( \mathcal{F} = \{ \log f_n \}_{n=1}^\infty \) a sequence on \( X \) satisfying (C1), (C2), (C3) and (C4). A measure \( \mu \in M(X, \sigma) \) is said to be an equilibrium measure for \( \mathcal{F} \) if
\[
P(\mathcal{F}) = h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n \, d\mu.
\]

**Definition 5.2.** Let \((X, \sigma)\) be a subshift on a countable alphabet and \( \mathcal{F} = \{ \log f_n \}_{n=1}^\infty \) a sequence on \( X \) satisfying (C1), (C2), (C3) and (C4). A measure \( \mu \in M(X, \sigma) \) is said to be Gibbs for \( \mathcal{F} \) if there exist constants \( C_0 > 0 \) and \( P \in \mathbb{R} \) such that for every \( n \in \mathbb{N} \) and every \( x \in [i_1 \ldots i_n] \) we have
\[
\frac{1}{C_0} \leq \frac{\mu([i_1 \ldots i_n])}{\exp(-nP)f_n(x)} \leq C_0.
\]

A Gibbs measure \( \mu \) for a continuous function \( \phi \) could satisfy \( h_\mu(\sigma) = \infty \) and \( \int \phi \, d\mu = -\infty \). In such a situation, the measure \( \mu \) is not an equilibrium measure for \( \phi \) (see [S3] for comments and examples).

Existence of Gibbs measure was studied in [Y1, Y2] for an almost-additive sequence on a topologically mixing countable Markov shift with BIP property and in [KR, Theorem 3.7] for a class of sub-additive Bowen sequences on the full shift on a countable alphabet satisfying (C2), (C3) and (C4). Here we will generalize these results by considering a finitely irreducible countable sofic shift. The main result of this section is the following.

**Theorem 5.1.** Let \((X, \sigma)\) be a finitely irreducible countable sofic shift. If \( \mathcal{F} = \{ \log f_n \}_{n=1}^\infty \) is a Bowen sequence on \( X \) satisfying (C1), (C2), (C3) and (C4), then there is a unique invariant ergodic Gibbs measure \( \mu \) for \( \mathcal{F} \). Moreover, if in addition
\[
\sum_{i \in \mathbb{N}} \sup \{ \log f_1(x) : x \in [i] \} \sup \{ f_1(x) : x \in [i] \} > -\infty,
\]
then \( \mu \) is the unique equilibrium measure for \( \mathcal{F} \) on \( X \).

**Remark 5.1.** By Proposition 4.4 (C4) is equivalent to \( P(\mathcal{F}) < \infty \).
Corollary 5.1. Let \((X, \sigma)\) be a finitely irreducible countable Markov shift and \(\mathcal{G} = \{\log g_n\}_{n=1}^\infty\) an almost-additive Bowen sequence on \(X\). If \(\mathcal{G}\) satisfies (C4), then there is a unique Gibbs measure \(\mu\) for \(\mathcal{G}\) and it is ergodic. Moreover, if in addition
\[
\sum_{i \in \mathbb{N}} \sup \{\log g_i(x) : x \in [i]\} \sup \{g_i(x) : x \in [i]\} > -\infty,
\]
then \(\mu\) is the unique equilibrium measure for \(\mathcal{G}\).

Proof. Lemma 3.1 implies that \(\mathcal{G}\) satisfies (C2) and (C3). Now apply Theorem 5.1.

Remark 5.2. Theorem 5.1 generalizes [Y1, Theorem 4.1] in which almost-additive Bowen sequences on finitely primitive countable Markov shifts are considered. If \(\mathcal{G} = \{\log g_n\}_{n=1}^\infty\) is an almost-additive Bowen sequence, then \(\sum_{i \in \mathbb{N}} \sup \{\log g_i(x) : x \in [i]\} \sup \{g_i(x) : x \in [i]\} > -\infty\) is equivalent to \(h_\mu(\sigma) < \infty\) where \(\mu\) is the Gibbs measure (see [Y2, Proposition 3.1]).

In Theorem 5.1, we study the case when \(W \neq \{\varepsilon\}\) (see Remark 2.5). Hence, throughout the rest of the section, without loss of generality we assume
(A1) \(F = \{\log f_n\}_{n=1}^\infty\) satisfies (C1), (C2) with some \(p \in \mathbb{N}\) and (C3) with a finite set \(W\) containing a nonempty word \(w^*\) of length \(p\), and
(A2) In Lemma 4.6, for all \(k \geq q\), \(w^* \in W\) appears in (4.12) for a pair of allowable words \(u, v\) of \(X_{I_k}\).

To see (A2), note that since \(W\) from (C3) contains \(w^*\) there exist \(N_1, N_2\) and a pair \(\bar{u}, \bar{v} \in B_{N_1}(X), \bar{v} \in B_{N_2}(X)\) such that \(\bar{u}w^*\bar{v}\) is an allowable word of \((N_1 + N_2 + p)\) satisfying (C2). In the proof of Lemma 4.6, we take \(S_{I_k}\) large enough so that it contains all the preimages of symbols that appear in \(\bar{u}\) and \(\bar{v}\).

The idea of the proof of Theorem 5.1 is similar to that of [Y1, Theorem 4.1], which in turn was proved using techniques of [MU2, Lemma 2.8] and [B2, Lemmas 1, 2 and Theorem 5]. The modification of the proof has to be adapted to the fact that condition (C2) replaces the lower bound condition (2.2) of an almost-additive sequence. We continue to use the notation from Lemma 4.6.

Theorem 5.2. [Fe4] Let \((X, \sigma)\) be an irreducible subshift on a finite alphabet. If \(F = \{\log f_n\}_{n=1}^\infty\) is a Bowen sequence on \(X\) satisfying (C1) and (C2), then there exists a unique Gibbs measure for \(F\). Moreover, it is the unique equilibrium measure for \(F\).

Proposition 5.1. For \(n \geq q\), there is a unique equilibrium measure for \(F|_{X_{I_n}}\) and it is Gibbs for \(F|_{X_{I_n}}\). Moreover, the Gibbs constant \(C_0\) (see Definition 5.2) can be chosen independently of \(X_{I_n}\).

Proof. The first part of Proposition 5.1 follows from Theorem 5.2. Indeed, note that since \(F\) is a Bowen sequence satisfying (C1), (C2), (C3) and (C4) and \(X_{I_n}\) contains all allowable words in \(W\) for \(n \geq q\), we have that \(F|_{X_{I_n}}\) is a sequence on \((X_{I_n}, \sigma_{X_{I_n}})\) satisfying (4.12) replacing \(D_{n,m}/M_{n+m+p}\) by \(D/M\).

In order to prove the second claim in Proposition 5.1 we will modify the proof of [Y1, Claim 4] considering equation (4.12). By the assumptions, any allowable word in \(W\) is an allowable word of \(X_{I_n}\) for all \(n \geq q\). Fix \(X_{I_n}, n \geq q\), and call it \(Z\). Define \(\alpha_n^Z = \sum_{i_1, \ldots, i_n \in B_n(z)} \sup \{f_{i_1, \ldots, i_n}(z) : z \in [i_1, \ldots, i_n]\}\). By the sub-additive property of \(\{\log c^f_n\}_{n=1}^\infty\), we have for \(l, n \in \mathbb{N}\) that
\[
\alpha_{n+l}^Z \leq c^l \alpha_n^Z \alpha_l^Z.
\]
Hence \(\{\log (c^Z \alpha_n^Z)\}_{n=1}^\infty\) is sub-additive. We claim that for some \(C_1 > 0\) the sequence \(\{\log (C_1 \alpha_n^Z)\}_{n=1}^\infty\) is super-additive. In order to show this, we adapt the arguments of the proof of [Y1, Claim 4] to
our setting. For \( l \in \mathbb{N} \), let \( \nu_l \) be the Borel probability measure on \( Z \) defined by

\[
\nu_l([i_1 \ldots i_l]) = \frac{\sup \{ f_i | z \in [i_1 \ldots i_l] \}}{\alpha_i^l}.
\]

By Lemma 4.6, for any allowable words \( u = u_1 \ldots u_m \) and \( v = v_1 \ldots v_l \) of \( Z \), \( n, l \in \mathbb{N} \), there exists \( w \in B_{|w|}(Z) \in W \), \( 0 \leq |w| \leq p \) such that \( uwv \) is an allowable word of \( Z \) and that

\[
\sup \{ f_{n+w+l} | z \in [uwv] \} \geq \frac{D}{M} \sup \{ f_n | z \in [u] \} \sup \{ f_l | z \in [v] \}.
\]

For a fixed \( \bar{u} \in B_n(Z) \), considering all possible \( v \in B_l(Z) \) with \( w \) satisfying (5.2) and then considering all possible \( \bar{u} \in B_n(Z) \), we obtain

\[
\sum_{i=0}^{p} \alpha_{n+l+i}^Z \geq \frac{D}{M} \alpha_n^Z \alpha_l^Z.
\]

Let \( D/M := D_1 \). Then for each \( n, l \in \mathbb{N} \), there exists \( 0 \leq i_1 \leq p \) such that \( \alpha_{n+l+i_1}^Z \geq (D_1 \alpha_{n+l+i_1}^Z)/(p + 1) \). By sub-additivity of \( \{ \log(e^C \alpha_n^Z) \}_n \), we obtain

\[
\alpha_{n+l+i_1}^Z \leq e^C \alpha_{n+l+i_1}^Z \leq e^C \alpha_n^Z \alpha_l^Z.
\]

Letting \( K = \max_{0 \leq i \leq p} Z(F) \), for any \( n, l \in \mathbb{N} \) we have

\[
\alpha_{n+l}^Z \geq D_1 \alpha_n^Z \alpha_l^Z /(e^C K (p + 1)).
\]

Let \( C_1 = D_1/(e^C K (p + 1)). \) Since \( P(F) = \lim_{n \to \infty} (1/n) \log \alpha_n^Z \), we use the argument in [Y1, Claim 4.1]. The sub-additivity of \( \{ \log(e^C \alpha_n^Z) \} \), the super-additivity of \( \{ \log(C_1 \alpha_n^Z) \} \), and \( Z_1(F) < \infty \) imply that

\[
C_1 \alpha_n^Z \leq e^{P(F) n} \leq e^C \alpha_n^Z.
\]

We now construct a Gibbs measure using similar arguments as those in the proof of [B2, Theorem 5]. For fixed \( u \in B_n(Z) \), \( m \in \mathbb{N} \), we define \( \alpha_{n+m}^Z \leq \sum_{u_{a_1} \ldots a_m \in B_{n+m}(Z)} \sup \{ f_{n+m} | z \in [ua_1 \ldots a_m] \} \).

**Lemma 5.1.** There exists \( C_2 > 0 \) such that for each fixed \( u \in B_n(Z) \), \( l > n + 2p \), we have

\[
\alpha_{l}^{Z,u} \geq C_2 \alpha_{l-n-2p}^{Z} \sup \{ f_n | z \in [u] \}.
\]

Note that \( C_2 \) is independent of \( Z \).

**Proof.** For the proof, see Section 5.2. \( \square \)

By the definition of the measure \( \nu_l \) and (C1), for a fixed \( u = u_1 \ldots u_n \in B_n(Z) \), \( n < l \), we have that,

\[
\nu_l([u]) \leq e^{C} \sup \{ f_n | z \in [u] \} \alpha_l^Z.
\]

Therefore, using (5.4), we obtain that for each \( z \in [u] \)

\[
\frac{\nu_l([u])}{e^{-nP(F) |z|} f_n |z|} \leq \frac{M \nu_l([u])}{e^{-nP(F) |z|} \sup \{ f_n | z \in [u] \}} \leq \frac{M e^{2C} \alpha_{l-n}^Z \alpha_n^Z}{\alpha_l^Z} \leq \frac{M e^{3C}}{C_1^2}.
\]

On the other hand, by Lemma 5.1 and (5.4), for each \( z \in [u] \), for \( l > n + 2p \),

\[
\frac{\nu_l([u])}{e^{-nP(F) |z|} f_n |z|} \geq \frac{\alpha_{l}^{Z,u}}{\alpha_l^Z e^{nP(F) |z|} \sup \{ f_n | z \in [u] \} \sup \{ f_l | z \in [v] \}} \geq C_1 C_2 e^{-2pP(F) |z| - C}.
\]
Noting that $e^{-2pP(F|z)} \geq e^{-2pP(F)}$ if $P(F) \geq 0$ and $e^{-2pP(F|z)} > 1$ if $P(F) < 0$, there exist $C_3 > 0, C_4 > 0$, both independent of $Z$, such that for all $l > n + 2p,$

\begin{equation}
C_3 \leq \frac{\nu([u])}{e^{-nP(F|z)} f_n|Z(z)} \leq C_4 \text{ for all } z \in [u].
\end{equation}

(5.5)

Since the set $Z$ is compact, there exists a subsequence $\{\nu_{n_k}\}_{k=1}^{\infty}$ of $\{\nu_n\}_{n=1}^{\infty}$ that converges to a measure $\nu$ and for all $z \in [u]$

\begin{equation}
C_3 \leq \frac{\nu([u])}{e^{-nP(F|z)} f_n|Z(z)} \leq C_4.
\end{equation}

(5.6)

Now let $\mu_n = (1/n) \sum_{i=1}^{n} \sigma^i \nu$. We claim that any weak limit point $\mu$ of $\{\mu_n\}_{n=1}^{\infty}$ is a $\sigma Z$-invariant Gibbs measure on $Z$.

For each fixed $u \in B_n(Z)$, define $\alpha^Z_{l+m}(u) = \sum_{a_1 \ldots a_l u \in B_l, x} \sup \{f_{l+m}|Z(z) : z \in [a_1 \ldots a_l u]\}.$

Then setting $l = m + i$, for $m \in \mathbb{N}, 0 \leq i \leq p$, we obtain that $\sum_{0 \leq i \leq p} \alpha^Z_{l+m+1}(u) \geq D_1 \alpha^Z_m \sup \{f_n|z(z) : z \in [u]\}.$

Therefore, there exists $0 \leq i_{n,m,u} \leq p$ such that

\begin{equation}
\alpha^Z_{n+m+i_{n,m,u}}(u) \geq (D_1/p + 1) \alpha^Z_m \sup \{f_n|z(z) : z \in [u]\}.
\end{equation}

Note that $i_{n,m,u}$ depends on $n, m$ and $u$. In the next lemma, we continue to use the above notation.

**Lemma 5.2.** There exists $C_5 > 0$ such that for any $0 \leq i \leq p$, any $m \in \mathbb{N}$ and $u \in B_n(Z)$ we have

\begin{equation}
\alpha^Z_{n+m+i}(u) \geq C_5 \alpha^Z_m \sup \{f_n|z(z) : z \in [u]\}.
\end{equation}

Note that $C_5$ is independent of $Z$.

**Proof.** The proof can be found in Section 5.2

Now we apply Lemma 5.2 to show that $\mu$ is $\sigma Z$-invariant. Let $u \in B_n(Z)$ be fixed and set $M_2 = \max\{0, P(F)\}$. Letting $l = m + i$ for $m \in \mathbb{N}$ and $0 \leq i \leq p,$

$\nu(\sigma^l[u]) = \sum_{v \in B_l(Z), v u \in B_{l+m}(Z)} \nu([v u]) \geq \sum_{v \in B_{l+m}(Z)} \frac{C_3}{M} e^{-(l+m+n)P(F|z)} \sup \{f_{l+m}|z(z) : z \in [v u]\} \geq \frac{C_3 C_5}{MC_4 e^C} e^{-p M_2} \nu([u]),$

where in the last inequality we use (5.4). Using (C1), similarly, we obtain

$\nu(\sigma^l[u]) \leq \frac{C_4 e^C M}{C_3} \nu([u]).$

Therefore, using the similar arguments as in the proof of [B2, Theorem 5], there exist $C_3, C_4 > 0$ such that for $u \in B_n(Z)$ and $x \in [u]$ we have

\begin{equation}
\bar{C}_3 \leq \frac{\mu([u])}{e^{-nP(F|z)} f_n|z(x)} \leq \bar{C}_4.
\end{equation}

(5.7)

Thus $\mu$ is a Gibbs measure on $Z$. It is $\sigma Z$-invariant because it is a weak limit of invariant measures. By Theorem 5.2, $\mu$ is the unique invariant ergodic Gibbs measure and the unique equilibrium measure for $F|z$. Hence, for $n \geq q$, if we let $\mu_n$ be the $\sigma|Z_n$-invariant Gibbs measure on $Z_n$, then it satisfies for each $k \in \mathbb{N}, u \in B_k(Z_n)$ and every $z \in [u],$

\begin{equation}
\bar{C}_3 \leq \frac{\mu_n([u])}{e^{-kP(F|z_n)} f_k|z_n(z)} \leq \bar{C}_4.
\end{equation}

(5.8)

Clearly $\bar{C}_3$ and $\bar{C}_4$ are independent of $Z_n$.
In the following proof, we continue to use the notation of the $\sigma|_{Z_{i_n}}$-invariant Gibbs measure $\mu_{i_n}$ on $Z_{i_n}$ satisfying (5.8). The idea in the rest of the proof is basically the same as in [Y1, Theorem 4.1]. However, techniques used here are slightly different, taking into account of (C2). We include some details for completeness.

**Proof of Theorem 5.1.** We show that the sequence $\{\mu_{i_n}\}_{n=q}^{\infty}$ of $\sigma$-invariant Borel probability measures on $X$ is tight. For this purpose, we apply Prohorov’s theorem to the sequence $\{\mu_{i_n}\}_{n=q}^{\infty}$. We note that the same proof of [Y1, Theorem 4.1] holds (see also the proof of [MU2, Lemma 2.7]). Here we only state how we modify using the notation of [Y1, Theorem 4.1].

We first note that in the proof the Gibbs property of $\mu_{i_n}$ and the property (C1) of $\mathcal{F}|_{Z_{i_n}}$ are applied. Secondly the fact that, for an irreducible countable sofic shift $X$, $X \cap \prod_{k \geq 1}[1, n_k]$ is a compact subset of $X$ is used (see proof of [Y1, Theorem 4.1] for details). Since we consider a finitely irreducible countable Markov shift $X$, there exist an irreducible countable Markov shift $\tilde{X}$ and one-block factor map $\pi: \tilde{X} \to X$ such that $|\pi^{-1}(i)| < \infty$ for each $i \in \mathbb{N}$. For a fixed $k$, we first consider preimages of $[1, n_k]$ and call it $P_{n_k}$. Note that $P_{n_k}$ is a finite set. Then $X \cap \prod_{k \geq 1} P_{n_k}$ is a compact subset of $\tilde{X}$. Thus $X \cap \prod_{k \geq 1}[1, n_k]$ is a compact subset of $X$.

Therefore, we conclude that there exists a convergent subsequence $\{\mu_{i_{n_k}}\}_{k=1}^{\infty}$ of $\{\mu_{i_n}\}_{n=q}^{\infty}$. We denote by $\mu$ a limit point of this subsequence. Then $\mu$ is $\sigma$-invariant on $X$. By (5.8), letting $t_{n_k} \to \infty$, we obtain for $n \in \mathbb{N}$, $u \in B_n(X)$ and each $x \in [u]$ that,

$$C_3 \leq \frac{\mu([u])}{e^{-nP(\mathcal{F})}} f_n(x) \leq C_4. \tag{5.9}$$

Therefore, $\mu$ is a Gibbs measure for $\mathcal{F}$ on $X$. Next we show that $\mu$ is ergodic. In order to show this we apply the following lemma.

**Lemma 5.3.** For fixed allowable words $u \in B_n(X), v \in B_l(X)$ and $t \in \mathbb{N},$

$$\sum_{u_{a_1} \cdots a_{t+1} v \in B_{n+l+t+1}(X), 0 \leq i \leq 2p} \sup \{f_{n+i+t+i}(x) : x \in [u a_1 \cdots a_{t+i} v]\} \geq D^2 \sup \{f_n(x) : x \in [u]\} \sup \{f_l(x) : x \in [v]\} Z_t(\mathcal{F}).$$

**Proof.** The proof can be found in Section 5.2. \hfill $\square$

Now we show that any invariant Gibbs measure for $\mathcal{F}$ is ergodic. In particular, in the following, we show that $\mu$ is ergodic by proving that there exists $C_0 > 0$ such that given $u \in B_n(X), v \in B_l(X)$ and $t \in \mathbb{N}$, there exists $0 \leq i_{u,v,t} \leq 2p$ such that $\mu([u] \cap \sigma^{-(n+l+t+i_{u,v,t})}([v])) \geq (C_0/(2p+1))\mu([u])\mu([v]).$

Note that the same proof holds for any invariant Gibbs measure for $\mathcal{F}$.

Define $\alpha_n = \sum_{i_1 \cdots i_n \in B_n(X)} \{f_n(x) : x \in [i_1 \cdots i_n]\}$. Let $M_2 = \max\{0, P(\mathcal{F})\}$. By applying Lemma 5.3,

$$\sum_{i=0}^{2p} \mu([u] \cap \sigma^{-(n+t+i)}([v])) \geq \sum_{i=0}^{2p} \sum_{u_{a_1} \cdots a_{t+i} v \in B_{n+l+i+t+1}(X)} \mu([u a_1 \cdots a_{t+i} v]) \geq \frac{C_3 e^{-(n+t+i)P(\mathcal{F})-2pM_2}}{M} \sum_{i=0}^{2p} \sum_{u_{a_1} \cdots a_{t+i} v \in B_{n+l+i+t+1}(X)} \sup \{f_{n+i+t+i}(x) : x \in [u a_1 \cdots a_{t+i} v]\} \geq \frac{C_3 D^2 e^{-(n+t+i)P(\mathcal{F})-2pM_2}}{M} \alpha_l \sup \{f_n(x) : x \in [u]\} \sup \{f_l(x) : x \in [v]\} \geq \frac{C_3 D^2 e^{-2pM_2}}{MC_4^2} \mu([u])\mu([v]),$$
where in the third inequality we use Lemma 5.3 and in the last inequality we use (5.9). Now letting $C_6 = (\bar{C}_4 e^{-2pM_z D^2})/(M \bar{C}_4 e^C)$, there exists $0 \leq i_{u,v,t} \leq 2p$ such that

$$\mu([u] \cap \sigma^{-(n+t+i_{u,v,t})}([v])) \geq (C_6/(2p + 1))\mu([u])\mu([v]).$$

The Gibbs property with ergodicity implies that $\mu$ is the unique invariant ergodic measure on $X$ that satisfies the Gibbs property for $\mathcal{F}$. Finally we show that, if in addition,

$$\sum_{i \in \mathbb{N}} \sup\{\log f_i(x) : x \in [i]\} \sup\{f_i(x) : x \in [i]\} > -\infty,$$

then the unique invariant ergodic Gibbs measure $\mu$ for $\mathcal{F}$ is the unique equilibrium measure for $\mathcal{F}$. We claim that

$$\sum_{i \in \mathbb{N}} \sup\{\log f_i(x) : x \in [i]\} \sup\{f_i(x) : x \in [i]\} > -\infty \text{ if and only if } -\sum_{i \in \mathbb{N}} \mu([i]) \log \mu([i]) < \infty.$$

To see this, by (5.9),

$$\sum_{i \in \mathbb{N}} \mu([i]) \log \mu([i]) \leq \sum_{i \in \mathbb{N}} \bar{C}_4 e^{-P(\mathcal{F})} \sup\{f_i(x) : x \in [i]\} \log(\bar{C}_4 e^{-P(\mathcal{F})} \sup\{f_i(x) : x \in [i]\})$$

$$\leq \bar{C}_4 e^{-P(\mathcal{F})} (-P(\mathcal{F}) + \log \bar{C}_4) \sum_{i \in \mathbb{N}} \sup\{f_i(x) : x \in [i]\} \log(\sup\{f_i(x) : x \in [i]\}).$$

Similarly, we can prove the other direction. Since for all $n \in \mathbb{N}$

$$h_\mu(\sigma) = -\lim_{n \to \infty} \frac{1}{n} \sum_{u_n \in B_n(X)} \mu([u_n]) \log \mu([u_n]) \leq -\frac{1}{n} \sum_{u_n \in B_n(X)} \mu([u_n]) \log \mu([u_n]),$$

we obtain that $h_\mu(\sigma) < \infty$. We note that for $n \in \mathbb{N}$,

$$\frac{1}{n} \int \log f_n d\mu \leq \frac{1}{n} \sum_{u_n \in B_n(X)} \sup\{\log f_n(x) : x \in [u_n]\} \mu([u_n]) \leq \frac{M}{n} \int \log f_n d\mu.$$

Using (5.9), a simple calculation shows that

$$h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu = P(\mathcal{F}).$$

Thus $\lim_{n \to \infty} (1/n) \int \log f_n d\mu > -\infty$. Hence $\mu$ is an equilibrium measure.

To show that $\mu$ is the unique equilibrium measure, we use the same arguments as in [KR] and only mention modified parts for our setting. As in [KR, Lemma 3.9], we first claim that if $\nu \neq \mu$ is an equilibrium measure for $\mathcal{F}$ then $\nu$ is absolutely continuous with respect to $\mu$. Observe that given a sequence $\{C_n\}_{n=1}^\infty$, where each $C_n$ is a union of cylinder sets of length $n$ of $X$, by using the concavity of $h(x) = -x \log x$ and the Gibbs property of $\mu$, we obtain

$$0 = n h_\nu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\nu - P(\mathcal{F}) \leq \int \log(f_n e^C) d\nu - nP(\mathcal{F}) - \sum_{w \in B_n(X)} \nu([w]) \log \nu([w])$$

$$\leq \log 2 + \nu([C_n]) \log(\frac{\mu([C_n])}{e^C C_3}) + \nu([X \setminus C_n]) \log(\frac{\mu([X \setminus C_n])}{e^C C_3}).$$

Applying the proof of [KR, Lemma 3.9] by using the above inequalities, we obtain the claim. Then we follow the same proof found in [KR] to show the uniqueness. \qed
5.2. Proofs of Lemmas 5.1, 5.2, and 5.3.

Proof of Lemma 5.1. Fix \( n \in \mathbb{N} \). It is direct from (5.2) that for any \( m \in \mathbb{N} \), \( u \in B_n(Z) \),
\[
\sum_{0 \leq i \leq p} \alpha_{n+m+i}^{Z,u} \geq D_1 \alpha_m^Z \sup \{ f_n | z(z) : z \in [u] \},
\]
where \( D_1 := D/M \). Thus, there exists \( 0 \leq i_{n,m,u} \leq p \) such that
\[
\alpha_{n+m+i_{n,m,u}}^{Z,u} \geq \frac{D_1}{p+1} \alpha_m^Z \sup \{ f_n | z(z) : z \in [u] \}.
\]
Fix \( l > n + 2p \) and set \( m = l - n - 2p \). Then there exists \( i_{n,m,u} \) such that
\[
\alpha_{l-2p+i_{n,m,u}}^{Z,u} \geq \frac{D_1}{p+1} \alpha_{l-2p-i_{n,m,u}}^{Z,u} \sup \{ f_n | z(z) : z \in [u] \}.
\]
Now take \( w^* \in W \) such that \( |w^*| = p \). Take \( a_1 \ldots a_{n-2p+i_{n,m,u}} \in B_{l-2p+i_{n,m,u}}(Z) \) and call it \( v \). Then by Lemma 4.6 there exists \( w \in W \) such that \( vww^* \) is an allowable word of \( Z \) and
\[
\sup \{ f_{l-2p+i_{n,m,u}} | z(z) : z \in [vww^*] \} \geq D_1 \sup \{ f_{l-2p+i_{n,m,u}} | z(z) : z \in [v] \} \sup \{ f_p | z(z) : z \in [w^*] \}.
\]
In the similar manner, we can take \( \tilde{w} \in W \) such that
\[
\sup \{ f_{l+i_{n,m,u}+q_1+q_2} | z(z) : z \in [vww* \tilde{w} w^*] \} \geq D_1 \sup \{ f_{l+i_{n,m,u}+q_1+q_2} | z(z) : z \in [\tilde{w} w^*] \} \sup \{ f_{p} | z(z) : z \in [w^*] \}.
\]
Let \( |w| = q_1, |\tilde{w}| = q_2 \) and write \( \tilde{w} w^* v w^* = w_1 \ldots w_{2p+q_1+q_2} \). Then using (C1),
\[
sup \{ f_{l+i_{n,m,u}+q_1+q_2} | z(z) : z \in [vww* \tilde{w} w^*] \} \leq e^{C} \sup \{ f_{l} | z(z) : z \in [v] \} \sup \{ f_{l+i_{n,m,u}+q_1+q_2} | z(z) : z \in [w_{2p+q_1+q_2}] \} \leq e^{3pC} \sup \{ f_{l} | z(z) : z \in [v] \} \max Z_1(\mathcal{F})^i,
\]
if \( i_{n,m,u} + q_1 + q_2 \geq 1 \). If \( i_{n,m,u} = q_1 = q_2 = 0 \), then the second line in the above inequalities is simplified. If we let \( M' = \max_{0 \leq i \leq 3p} Z_1(\mathcal{F})^i \), then
\[
sup \{ f_{l} | z(z) : z \in [v] \} \geq \frac{D_1^2}{e^{3pC} M' M^2} \sup \{ f_{l+i_{n,m,u}} | z(z) : z \in [v] \} \sup \{ f_{p} | z(z) : z \in [w^*] \} \sup \{ f_{p} | z(z) : z \in [w^*] \} \sup \{ f_{p} | z(z) : z \in [w^*] \} \sup \{ f_{p} | z(z) : z \in [w^*] \},
\]
where in the last inequality we use the fact that \( \mathcal{F} \) is a Bowen sequence. Let \( \bar{m} = \min_{w \in W} \sup \{ f_{p} | z(z) : z \in [w^*] \} \). Then summing over all allowable words \( a_1 \ldots a_{l-n-2p+i_{n,m,u}} \), such that \( a_1 \ldots a_{l-n-2p+i_{n,m,u}} \in B_{l-2p+i_{n,m,u}}(Z) \), we obtain that
\[
\alpha_{l}^{Z,u} \geq \frac{\sup \{ f_{p} | z(z) : z \in [w^*] \}^2 D_1^2}{e^{3pC} M' M^2 (p+1)} \alpha_{l-2p+i_{n,m,u}}^{Z,u} \geq \frac{\bar{m} D_1^2}{e^{3pC} M' M^2 (p+1)} \alpha_{l-2p+i_{n,m,u}}^{Z,u},
\]
and combining with (5.10) the result follows.

Proof of Lemma 5.2. Fix \( n, m \in \mathbb{N} \) and \( u \in B_n(Z) \). There exists \( 0 \leq i_{n,m,u} \leq p \), such that \( \alpha_{n+m+i_{n,m,u}}^{Z,u} \geq (D_1/(p+1)) \alpha_m^Z \sup \{ f_{n} | z(z) : z \in [u] \} \). We first consider the case when \( p \geq 2 \). Let \( i_{n,m,u} = i_0 \) and assume \( i_0 \geq 1 \). Let \( a_1 \ldots a_{m+i_0}u \in B_{n+m+i_0}(Z) \) and call it \( v \). Let \( w^* = w_1^* \ldots w_p^* \in W \) such that \( |w^*| = p \). Take \( C = \max_{0 \leq i \leq 2p} Z_1(\mathcal{F})^i \). Also, take \( D_W = (1/M) \min_{w \in W} \sup \{ f_{|w|} | x(z) : x \in [w] \} \). Then by Lemma 4.6 there exists \( w \in W \) such that
\[
\sup \{ f_{n+m+i_0+p+|w|} | z(z) : z \in [w^* w^*] \} \geq \frac{D}{M} \sup \{ f_{p} | z(z) : z \in [w^*] \} \sup \{ f_{n+m+i_0} | z(z) : z \in [w] \}.
\]
First we show that there exists $C_1 > 0$ such that for any $j \in \mathbb{N}$ such that $i_0 + j \leq p$,

$$
\alpha_{n+m+i_0+j}^Z(u) \geq C_1 \alpha_{n+m+i_0}^Z(u).
$$

(5.12)

Fix $j$ and we consider two cases depending on $|w|, |w| > j$ and $|w| \leq j$. Let $w = w_1 \ldots w_k$ and suppose $k > j$. Since

$$
\sup \{ f_{n+m+i_0+p+k} | z \} : z \in [w^* w v] \\
\leq e^C \sup \{ f_{p-k} | z \} : z \in [w^* w_1 \ldots w_{k-j}] \} \sup \{ f_{n+m+i_0+j} | z \} : z \in [w_{k-j+1} \ldots w_k v] \\
\leq e^{2pC} C \sup \{ f_{n+m+i_0+j} | z \} : z \in [w_{k-j+1} \ldots w_k v] \\
$$

applying (5.11), we obtain

$$
\sup \{ f_{n+m+i_0+j} | z \} : z \in [w_{k-j+1} \ldots w_k v] \\
\geq \frac{D}{e^{2pC} C} \sup \{ f_p | z \} : x \in [w^*] \} \sup \{ f_{n+m+i_0} | z \} : z \in [v].
$$

(5.13)

Next suppose $k \leq j \leq p - i_0$. Then

$$
\sup \{ f_{n+m+i_0+p+k} | z \} : z \in [w^* w v] \\
\leq e^C \sup \{ f_{p-j-k} | z \} : z \in [w^* w_{p-(j-k)}] \} \sup \{ f_{n+m+i_0+j} | z \} : z \in [w^* w_{p-(j-k)+1} \ldots w_k v] \\
$$

Hence

$$
\sup \{ f_{n+m+i_0+j} | z \} : z \in [w^* w_{p-(j-k)+1} \ldots w_k v] \\
\geq \frac{D}{e^{2pC} C} \sup \{ f_p | z \} : x \in [w^*] \} \sup \{ f_{n+m+i_0} | z \} : z \in [v].
$$

(5.16)

For each $a_1 \ldots a_{m+i_0} u \in B_{n+m+i_0}(Z)$, finding $w$ satisfying (5.11) and applying (5.14) or (5.18), we obtain

$$
\alpha_{n+m+i_0+j}^Z(u) \geq \frac{DDW}{e^{2pC} C} \alpha_{n+m+i_0}^Z(u).
$$

(5.19)

Next we show that there exists $C'_1 > 0$ such that for each $j \in \mathbb{N}$, $0 \leq j \leq i_0 \leq p$, we have

$$
\alpha_{n+m+i_0-j}^Z(u) \geq C'_1 \alpha_{n+m+i_0}^Z(u). \text{ Fix } j. \text{ For each } v = a_1 \ldots a_{m+i_0} u \in B_{n+m+i_0}(Z),
$$

$$
\sup \{ f_j | z \} : z \in [a_1 \ldots a_j] \} \sup \{ f_{n+m+i_0-j} | z \} : z \in [a_{j+1} \ldots a_{m+i_0} u] \}
$$

$$
\geq e^{-C} \sup \{ f_{n+m+i_0} | z \} : z \in [v] \}
$$

(5.20)

Noting that $\sup \{ f_j | z \} : z \in [a_1 \ldots a_j] \} \leq e^{(p-1)C}$, we obtain

$$
\alpha_{n+m+i_0-j}^Z(u) \geq \frac{1}{C'^p C} \alpha_{n+m+i_0}^Z(u).
$$

For the case when $i_0 = 0$, we make similar arguments. We note that (5.16) is not used (calculation is simplified) when $i_0 = 0, j = p$ and $k = 0$. For the case when $p = 1$, we consider the case when $i_0 = 0, 1$ in a similar manner. Hence we obtain the results.

□

Proof of Lemma 5.3. For a fixed $t \in \mathbb{N}$, fix $c \in B_t(X)$. Then given $v$ and $c$, there exists $w_1 \in B_{|w_1|}(X), 0 \leq |w_1| \leq p$ such that

$$
\sup \{ f_{t+|w_1|+t} | x \} : x \in [cw_1 v] \} \geq D \sup \{ f_t | x \} : x \in [c] \} \sup \{ f_t | x \} : x \in [v].
$$

(5.21)
Therefore, for fixed \( u \) and \( cw_1v \) above, there exists \( w_2 \in B_{|w_2|}(X) \), \( 0 \leq |w_2| \leq p \) such that

\[
(5.22) \quad \sup\{f_{n+|w_2|+t+|w_1|+i}(y) : y \in [uw_2cw_1v]\} \\
(5.23) \quad \geq D \sup\{f_n(x) : x \in [u]\} \sup\{f_{i+|w_1|+i}(x) : x \in [cw_1v]\} \\
(5.24) \quad \geq D^2 \sup\{f_n(x) : x \in [u]\} \sup\{f_i(y) : x \in [c]\} \sup\{f_i(x) : x \in [v]\}.
\]

Summing over all allowable words \( c \in B_l(X) \), each of which satisfies (5.21) and (5.22)-(5.24) with some \( w_1, w_2 \), we obtain the result. \( \Box \)

6. Application to Hidden Gibbs measures on shift spaces over countable alphabets

In this section, we apply the results in the previous sections to problems on factors of invariant Gibbs measures. Let \( \pi : X \to Y \) be a one-block factor map between countable sofic shifts such that \( |\pi^{-1}(i)| < \infty \) for each \( i \in \mathbb{N} \). For every measure \( \mu \in M(X, \sigma) \) the map \( \pi \) induces a measure \( \nu \in M(Y, \sigma) \) defined by

\[ \nu(B) = \pi \mu(B) := \mu(\pi^{-1}B), \]

where \( B \subset Y \) is any Borel set. If the original measure \( \mu \) is a Gibbs measure then the measure \( \nu \), which is a factor of a Gibbs measure, is sometimes called hidden Gibbs measure. Determining the properties of \( \pi \mu \) is a problem that has been addressed in different settings. In statistical mechanics, it has been found that non-Gibbs measures can occur as images of Gibbs measures under Renormalization Group transformations and generalizations of Gibbs measures have been studied (see for example [E, EFS]).

The study of this type of measure also has attracted a great deal of attention in dynamical systems. For an overview of the subject, see the survey article by Boyle and Petersen [BP]. The factor of the Gibbs measure for a continuous function need not be Gibbs for a continuous function but may be for a sequence of continuous functions.

The main goal of this section is to study factors of Gibbs measures on finitely irreducible countable sofic shifts. Technically, we make use of the thermodynamic formalism developed in the article, in particular the results in Section 5 and apply a similar approach as in [Y2]. Let \((X, \sigma_X)\) and \((Y, \sigma_Y)\) be finitely irreducible countable sofic shifts. For a one-block factor map \( \pi : X \to Y \), \( n \in \mathbb{N} \), \( y = (y_1, \ldots, y_n, \ldots) \in Y \), let \( E_n(y) \) be a set consisting of exactly one point from each cylinder \([x_1 \ldots x_n]\) such that \( \pi(x_1 \ldots x_n) = y_1 \ldots y_n \). Given a sequence \( F = \{\log f_n\}_{n=1}^{\infty} \) on \( X \), define

\[ g_n(y) = \sup_{E_n(y)} \left\{ \sum_{x \in E_n(y)} f_n(x) \right\}. \]

We continue to use the notation in this section. Recall that we identify the set of a countable alphabet with \( \mathbb{N} \).

**Theorem 6.1.** Let \((X, \sigma_X)\) be a finitely irreducible countable sofic shifts, \((Y, \sigma_Y)\) a subshift on a countable alphabet and \( \pi : X \to Y \) a one-block factor map such that for each \( i \in \mathbb{N} \), \( |\pi^{-1}(i)| < \infty \). Let \( F = \{\log f_n\}_{n=1}^{\infty} \) be an almost-additive Bowen sequence on \( X \). If \( Z_1(F) < \infty \), then there exists a unique invariant ergodic Gibbs measure \( \mu \) for \( F \) and the projection \( \pi \mu \) of the measure \( \mu \) is the unique invariant ergodic Gibbs measure for \( G = \{\log g_n\}_{n=1}^{\infty} \). Moreover,

\[
(6.1) \quad P_G(F) = P(F) = \sup_{\mu \in M(X, \sigma_X)} \left\{ h_\mu(\sigma_X) + \lim_{n \to \infty} \frac{1}{n} \int f_n d\mu : \lim_{n \to \infty} \frac{1}{n} \int \log f_n d\mu > -\infty \right\} \\
(6.2) \quad = \sup_{\nu \in M(Y, \sigma_Y)} \left\{ h_\nu(\sigma_Y) + \lim_{n \to \infty} \frac{1}{n} \int \log g_n d\nu : \lim_{n \to \infty} \frac{1}{n} \int \log g_n d\nu > -\infty \right\} \\
(6.3) \quad = P(G) < \infty.
\]
In addition, if \( \sum_{i \in \mathbb{N}} \sup \{ \log f_i(x) : x \in [i] \} > -\infty \), then \( \mu \) is the unique equilibrium measure for \( \mathcal{F} \) and \( \pi \mu \) is the unique equilibrium measure for \( \mathcal{G} \). In particular, if \((X, \sigma_X)\) is a factor of a finitely primitive countable Markov shift, then \( \limsup \) in the definition (2.5) of \( P_G(\mathcal{F}) \) can be replaced by \( \lim \).

**Remark 6.1.** In [Y2, Theorem 3.1], almost-additive Bowen sequences on finitely primitive subshifts are considered and the proof of Theorem 6.1 generalizes it for those on finitely irreducible subshifts.

**Remark 6.2.** Another approach to show [Y2, Theorem 3.1] is to apply [Fe4, Proposition 3.7] concerning relative variational principle. However, in [Fe4, Proposition 3.7], shift spaces are assumed to be compact (subshifts on finite alphabets) and so we cannot apply the proposition directly to show Theorem 6.1.

**Proof of Theorem 6.1.** We first note that \( Y \) is an irreducible countable sofic shift because \( X \) is an irreducible countable sofic shift. Since \( X \) is finitely irreducible, there exist \( p \in \mathbb{N} \) and a finite set \( W_1 \) defined in Definition 2.3.

By Lemma 3.1 the sequence \( \mathcal{F} = \{ \log f_n \}_{n=1}^\infty \) satisfies (C1), (C2) with \( p \), (C3) with \( W_1 \) and (C4). Hence, by Theorem 5.1, there exists a unique invariant ergodic Gibbs measure \( \mu \) for \( \mathcal{F} = \{ \log f_n \}_{n=1}^\infty \). Clearly \( \mathcal{G} = \{ \log g_n \}_{n=1}^\infty \) is a Bowen sequence. We show that \( \mathcal{G} \) satisfies (C1), (C2), (C3) and (C4). By [Y2, Lemma 3.4], the sequence \( \mathcal{G} \) satisfies (C1). To verify that condition (C4) is fulfilled, note that for each symbol \( i \in \mathbb{N} \) in \( Y \) we have that

\[
\sup \{ g_1(y) : y \in [i] \} \leq \sum_{j \in \mathbb{N}, \pi(j) = i} \sup \{ f_1(x) : x \in [j] \}.
\]

Then \( Z_1(\mathcal{G}) \leq \sum_{i \in \mathbb{N}} \sum_{j \in \mathbb{N}, \pi(j) = i} \sup \{ f_1(x) : x \in [j] \} = Z_1(\mathcal{F}) < \infty \). Next we show that \( \mathcal{G} \) satisfies (C2). For \( y = (y_1, \ldots, y_n, \ldots) \in Y \), by the Bowen property,

\[
\frac{1}{M} \sum_{x_1 \ldots x_n \in B_n(X), \pi(x_1 \ldots x_n) = y_1 \ldots y_n} \sup \{ f_n(x) : x \in [x_1 \ldots x_n] \} \leq g_n(y)
\]

\[
\leq \sum_{x_1 \ldots x_n \in B_n(X), \pi(x_1 \ldots x_n) = y_1 \ldots y_n} \sup \{ f_n(x) : x \in [x_1 \ldots x_n] \}.
\]

We note that if \( X \) is an irreducible subshift on a finite alphabet (compact case), then [Fe4, Lemma 5.7] and (6.5) imply that \( \mathcal{G} \) satisfies (C1) and (C2). For completeness, we present a proof in this non-compact setting. Since \( p \) is a weak specification number of \( X \), \( Y \) also satisfies the weak specification property with the specification number \( p \). In particular, for given \( u \in B_n(Y) \) and \( v \in B_m(Y) \), \( n, m \in \mathbb{N} \), there exists \( w_1 \in \pi(W_1) \) (see Example 3.3 for the notation), \( 0 \leq |w_1| \leq p \) such that \( uvw \) is an allowable word of \( Y \). For \( w \in \pi(W_1) \) such that \( uvw \) is allowable in \( Y \), pick a \( y_w \in [uvw] \). Note that given any \( x_1 \ldots x_m, x'_1 \ldots x'_m \in \pi^{-1}(u) \) and \( x'_1 \ldots x'_m \in \pi^{-1}(v) \), there exists \( w_0 \in W_1 \) such that \( x_1 \ldots x_n w_0 x'_1 \ldots x'_m \) is allowable with the property (C2) and \( \pi(x_1 \ldots x_n w_0 x'_1 \ldots x'_m) = u \pi(w_0) v \).
Then
\[
\sum_{w \in \pi(W_1)} \sup\{g_{n+m+|w|}(y) : y \in [uwv]\} \geq \sum_{w \in \pi(W_1)} g_{n+m+|w|}(y_w)
\]
\[
\geq \sum_{w \in \pi(W_1)} \frac{1}{M} \sum_{x_1 \ldots x_n \bar{w}x'_1 \ldots x'_m \in B_{n+m+|w|}(X)} \sup\{f_{n+|w|+m}(x) : x \in [x_1 \ldots x_n \bar{w}x'_1 \ldots x'_m]\}
\]
\[
\geq \frac{1}{M} \sum_{x_1 \ldots x_n \bar{w}x'_1 \ldots x'_m \in B_{n+m+|w|}(X)} D \sup\{f_n(x) : x \in [x_1 \ldots x_n]\} \sup\{f_m(x) : x \in [x'_1 \ldots x'_m]\}
\]
\[
\geq \frac{D}{M} \left( \sum_{x_1 \ldots x_n \in B_n(X)} \sup\{f_n(x) : x \in [x_1 \ldots x_n]\} \right) \left( \sum_{x'_1 \ldots x'_m \in B_m(X)} \sup\{f_m(x) : x \in [x'_1 \ldots x'_m]\} \right)
\]
\[
\geq \frac{D}{M} \sup\{g_n(y) : y \in [u]\} \sup\{g_m(y) : y \in [v]\},
\]
where in the third inequality we take $\bar{w} \in W_1$ such that (C2) holds with $x_1 \ldots x_n \bar{w}x'_1 \ldots x'_m$. Therefore, there exists $w_1 \in \pi(W_1)$ such that $uwv$ is allowable in $Y$ and
\[
(6.6) \quad \sup\{g_{n+|w|+m}(y) : y \in [uwv]\} \geq \frac{D}{M|\pi(W_1)|} \sup\{g_n(y) : y \in [u]\} \sup\{g_m(y) : y \in [v]\}.
\]

Hence $G$ satisfies (C2) with the same value of $p$ that appears in the weak specification and (C3) with $W = \pi(W_1)$. By Theorem 5.1 the sequence $G$ has a unique invariant Gibbs measure $\nu$. The second and fourth equalities in Theorem 6.1 hold because of the variational principle.

To complete the proof of the theorem, we apply ideas found in the proof of [Y2, Theorem 3.1]. Let $\mu$ be the equilibrium measure for $F$. To show that that $\pi\mu = \nu$, observe that the proof of [Y2, Theorem 3.7] holds in our setting because of the definition of the Gibbs measure. Hence, if we define $g_n(y) = g_n(y)e^{-nP(F)}$ and $G = \{\log g_n\}_{n=1}^\infty$, then there is a unique invariant Gibbs measure $\bar{\nu}$ for $G$ such that $\pi\mu = \bar{\nu}$. Hence $\pi\mu = \nu$ and it is the unique Gibbs measure for $G$. By the definition of topological pressure, it is easy to see that $Z_n(G) \leq Z_n(F)$ and $Z_n(F) \leq MZ_n(G)$. Thus $P(F) = P(G)$. Finally, we show that $\nu$ is a unique equilibrium measure by showing that
\[
\sum_{x \in \mathbb{N}} \sup\{\log g_1(y) : y \in [i]\} \sup\{g_1(y) : y \in [i]\} > -\infty.
\]
Assume that $\sum_{x \in \mathbb{N}} \sup\{f_1(x) : x \in [x_1]\} \sup\{\log f_1(x) : x \in [x_1]\} > -\infty$.

Using the definition of $g_1$ and the fact that $F$ is a Bowen sequence we obtain that
\[
\sup\{g_1(y) : y \in [y_1]\} \sup\{\log g_1(y) : y \in [y_1]\}
\]
\[
\geq \frac{1}{M} \left( \sum_{x_1 \in \mathbb{N}} \sup\{f_1(x) : x \in [x_1]\} \right) \log \left( \frac{1}{M} \sum_{x_1 \in \mathbb{N}} \sup\{f_1(x) : x \in [x_1]\} \right)
\]
\[
\geq \frac{1}{M} \left( \log \frac{1}{M} \right) \sum_{x_1 \in \mathbb{N}} \sup\{f_1(x) : x \in [x_1]\}
\]
\[
+ \frac{1}{M} \sum_{x_1 \in \mathbb{N}} \sup\{f_1(x) : x \in [x_1]\} \sup\{\log f_1(x) : x \in [x_1]\}.
\]
Therefore, summing over all allowable $y_1 \in \mathbb{N}$, we obtain the result. Applying Theorem 5.1 we have that $\nu$ is the unique equilibrium measure for $\mathcal{G}$. For the last statement, we apply Proposition 4.4.

**Theorem 6.2.** Let $(X, \sigma_X)$ be a finitely irreducible countable sofic shift, $(Y, \sigma_Y)$ a subshift on a countable alphabet and $\pi: X \to Y$ a one-block factor map such that for each $i \in \mathbb{N}$, $|\pi^{-1}(i)| < \infty$. Let $\mathcal{F} = \{\log f_n\}_{n=1}^\infty$ be an almost-additive sequence on $X$ with tempered variation. Then

$$P_{\mathcal{G}}(\mathcal{F}) = P(\mathcal{F}) = \sup_{\mu \in M(X, \sigma_X)} \left\{ h_\mu(\sigma_X) + \limsup_{n \to \infty} \frac{1}{n} \int f_n \, d\mu : \limsup_{n \to \infty} \frac{1}{n} \int f_n \, d\mu > -\infty \right\}$$

(6.7)

$$= \sup_{\nu \in M(Y, \sigma_Y)} \left\{ h_\nu(\sigma_Y) + \limsup_{n \to \infty} \frac{1}{n} \int g_n \, d\nu : \limsup_{n \to \infty} \frac{1}{n} \int g_n \, d\nu > -\infty \right\}$$

(6.8)

$$= P(\mathcal{G}).$$

(6.9)

If $\sup f_1 < \infty$, then $\limsup$ in the above equations can be replaced by $\lim$.

**Proof.** If $\mathcal{F}$ has tempered variation, (6.6) is replaced by

$$\sup\{g_{n+|w_1+m}(y) : y \in [uuv]\} \geq \frac{e^{-C Q}}{M_n + m + p M_n M_m M_p \pi(W_1)} \sup\{g_n(y) : y \in [u]\} \sup\{g_m(y) : y \in [v]\},$$

where $Q$ is defined for $\mathcal{F}$ as in Lemma 3.1. Applying Corollary 4.2 and Theorem 4.3, we obtain (6.7) and (6.9). To show $P(\mathcal{F}) = P(\mathcal{G})$, we make similar arguments as in the proof of Theorem 6.1. □

**Remark 6.3.** We do not know the existence of equilibrium measures for $\mathcal{F}$ and $\mathcal{G}$ in Theorem 6.2.

Next we consider the images of factors of Gibbs measures for single functions. Recall the definition of functions in the Bowen class from Section 2.

**Corollary 6.1.** Let $(X, \sigma_X)$ be a finitely irreducible countable sofic shift, $(Y, \sigma_Y)$ a subshift on a countable alphabet and $\pi: X \to Y$ a one-block factor map such that for each $i \in \mathbb{N}$, $|\pi^{-1}(i)| < \infty$. Let $f \in C(X)$ be in the Bowen class and suppose $Z_1(f) < \infty$. Then there exists a unique invariant ergodic Gibbs measure $\mu$ for $f$. Setting $f_n = e^{S_n(f)}$ in $\mathcal{G}$, the projection $\pi \mu$ of the measure $\mu$ is the unique invariant Gibbs measure for $\mathcal{G} = \{\log g_n\}_{n=1}^\infty$. Then

$$P_{\mathcal{G}}(f) = P(f) = \sup_{\mu \in M(X, \sigma_X)} \left\{ h(\mu) + \int f \, d\mu : \int f \, d\mu > -\infty \right\}$$

(6.10)

$$= \sup_{\nu \in M(Y, \sigma_Y)} \left\{ h_\nu(\sigma_Y) + \limsup_{n \to \infty} \frac{1}{n} \int g_n \, d\nu : \limsup_{n \to \infty} \frac{1}{n} \int g_n \, d\nu > -\infty \right\}$$

(6.11)

$$= P(\mathcal{G}) < \infty.$$ (6.12)

In addition, if $\sum_{i \in \mathbb{N}} \sup\{\log f(x) : x \in [i]\} \sup\{f(x) : x \in [i]\} > -\infty$, then $\mu$ is the unique equilibrium measure for $f$ and $\pi \mu$ is the unique equilibrium measure for $\mathcal{G}$.

**Proof.** The result is clear by applying Theorem 6.1. □

**Remark 6.4.** This is a generalization of [Y2, Corollary 3.2].
7. Other applications

7.1. Product of matrices and maximal Lyapunov exponents. A natural and interesting application of the non-additive version of thermodynamic formalism is the study of the norm of products of matrices. Indeed, let $M_d(\mathbb{R})$ be the set of real valued $d \times d$ matrices and $\| \cdot \|$ be a sub-multiplicative norm. Let $\{A_1, A_2, \ldots \}$ be a countable set in $M_d(\mathbb{R})$. Let $(X, \sigma)$ be a finitely irreducible countable sofic shift. If $w = (i_1, i_2, \ldots) \in X$, define the sequence of functions $\Phi = \{\log \phi_n\}_{n=1}^{\infty}$ by

$$
\phi_n(w) = \|A_{i_n} \cdots A_{i_2} A_{i_1}\|.
$$

Since

$$
\|AB\| \leq \|A\| \|B\|,
$$

the sequence $\Phi$ is sub-additive. It is a direct consequence of the sub-additive ergodic theorem [Ki] that if $\mu \in M(X, \sigma)$ is an ergodic measure, then for $\mu$-almost every $w \in X$

$$
\lim_{n \to \infty} \frac{1}{n} \int \log \phi_n \, d\mu = \lim_{n \to \infty} \frac{1}{n} \log \phi_n(w).
$$

The number

$$
\lambda(w) := \lim_{n \to \infty} \frac{1}{n} \log \phi_n(w),
$$

is called maximal Lyapunov exponent of $w$, whenever the limit exists. This number was originally studied in the context in which $X$ is the full shift on a finite alphabet with a finite collection matrices with strictly positive entries (see the work by Furstenberg and Kesten from 1960 [FK]). Ever since, the assumptions on the space and on the matrices has been generalized in wide ranges. The techniques developed in this article allow for another generalization that can be thought of as a non-compact version of the results obtained by Feng in [Fe3].

**Proposition 7.1.** Let $(X, \sigma)$ be a finitely irreducible countable sofic shift. Let $\{A_1, A_2, \ldots \}$ be a countable set of matrices in $M_d(\mathbb{R})$ having non-negative entries. Let $\Phi = \{\log \phi_n\}_{n=1}^{\infty}$ be the sequence of functions such that $\phi_n : X \to \mathbb{R}$ is defined by $\phi_n(w) = \|A_{i_n} \cdots A_{i_2} A_{i_1}\|$. If $\Phi$ satisfies (C2), (C3) and (C4), then there exists a unique invariant ergodic Gibbs measure $\mu$ for $\Phi$. Moreover, if in addition

$$
\sum_{i=1}^{\infty} \|A_i\| \log \|A_i\| > -\infty
$$

then $\mu$ is the unique equilibrium measure for $\Phi$ on $X$, that is

$$
P(\Phi) = h_\mu(\sigma) + \lim_{n \to \infty} \frac{1}{n} \int \log \phi_n \, d\mu.
$$

Note that $\phi_n$ is constant in cylinders of length $n$, therefore the Bowen condition is satisfied. Proposition 7.1 is an extension of [Y1, Proposition 7.1] in which the same conclusion was obtained under the assumption that $X$ is a countable Markov shift satisfying the BIP condition and $\Phi$ is almost-additive.

7.2. The singular value function. Thermodynamic formalism has been used, at least since the mid 1970s, to study the (Hausdorff) dimension of certain dynamically defined sets. This approach has been rather successful when the dynamical system is conformal. However, in dimension two (or higher) where a typical dynamical system is non-conformal the results obtained are fairly weak. With the purpose of obtaining better estimates on the dimension of non-conformal repellers, Falconer [F1] introduced the singular value function. The singular values $s_1(A), s_2(A)$ of a $2 \times 2$ matrix $A$ are the eigenvalues, counted with multiplicities, of the matrix $(A^* A)^{1/2}$, where $A^*$ denotes the transpose of $A$. The singular values can be interpreted as the length of the semi-axes of the ellipse which is the image of the unit ball under $A$. 

Let \( f : \mathbb{R}^2 \to \mathbb{R}^2 \) be a \( C^1 \) map and let \( \Lambda \subset \mathbb{R}^2 \) be a repeller of \( f \). That is, the set \( \Lambda \) is a (not necessarily compact), \( f \)-invariant, and the map \( f \) is expanding on \( \Lambda \), i.e., there exist \( c > 0 \) and \( \beta > 1 \) such that
\[
\|d_x f^n(v)\| \geq c\beta^n\|v\|,
\]
for every \( x \in \Lambda \), \( n \in \mathbb{N} \) and \( v \in T_x \mathbb{R}^2 \). We will also assume that there exists an open set \( U \subset \mathbb{R}^2 \) such that \( \Lambda \subset U \) and \( \Lambda = \cap_{n \in \mathbb{N}} f^n(U) \) and that \( f \) restricted to \( \Lambda \) can be coded by an irreducible countable sofic shift. For each \( x \in \mathbb{R}^2 \) and \( v \in T_x \mathbb{R}^2 \), we define the Lyapunov exponent of \( (x, v) \) by
\[
\lambda(x, v) := \limsup_{n \to \infty} \frac{1}{n} \log \|d_x f^n v\|.
\]
For each \( x \in \mathbb{R}^2 \), there exists a positive integer \( s(x) \leq 2 \), numbers \( \lambda_1(x) \geq \lambda_2(x) \), and linear subspaces
\[
\{0\} = E_{s(x)+1}(x) \subset E_{s(x)}(x) \subset E_1(x) = T_x \mathbb{R}^2,
\]
such that
\[
E_i(x) = \{ v \in T_x \mathbb{R}^2 : \lambda(x, v) = \lambda_i(x) \}
\]
and \( \lambda(x, v) = \lambda_i(x) \) if \( v \in E_i(x) \setminus E_{i+1}(x) \). The functions, \( \phi_{i,n} : \Lambda \to \mathbb{R} \) are defined by
\[
\phi_{i,n}(x) = \log s_i(d_x f^n)
\]
and called singular value functions. It follows from Oseledets’ multiplicative ergodic theorem that for each finite \( f \)-invariant measure \( \mu \) there exists a set \( X \subset \mathbb{R}^2 \) of full \( \mu \) measure such that
\[
\lim_{n \to \infty} \frac{\phi_{i,n}(x)}{n} = \lim_{n \to \infty} \frac{1}{n} \log s_i(d_x f^n) = \lambda_i(x). \tag{7.1}
\]
It was proved by Barreira and Gelfert [BG, Proposition 4] that if the dynamical system \( f \) has dominated splitting (see [B3, p.234] for a precise definition) and \( \Lambda \) is compact then the sequences \( \{\phi_{i,n}\}_{n=1}^\infty \) are almost-additive. The methods developed in this article allow us to study the singular value function in a broader context. In particular, it is a consequence of the variational principle that

**Proposition 7.2.** Let \((f, \Lambda)\) be a non-conformal repeller that can be coded by an irreducible countable sofic shift. If the singular value functions \( \Phi \) satisfy (C2), (C3) and (C4), then there exists a unique invariant ergodic Gibbs measure \( \mu \) for \( \Phi \).

We stress that Gibbs measures are of particular importance in the dimension theory of dynamical systems.
